VIRAL INFECTIONS OF RESPIRATORY TRACT

Their Treatment and Prevention

HOBART A. REIMANN, M.D.
Philadelphia

This discussion deals with acute, self-limiting, chiefly airborne diseases of known or presumed viral origin affecting predominantly the respiratory tract, ordinarily called colds, grip or influenza, and with certain newly delineated ones. There is hardly any need to recall the prevalence of the diseases in question or how little can be done for their prevention and cure. They account for most of the home visits (32 per cent) and provide the second most common reason (15 per cent) for office visits to general practitioners.[1] The average person is said to suffer from one to four bouts each year, accounting for about two hundred and fifty million infections annually in the United States.[2] Infections of the respiratory tract cause more loss of time from industry and from schools than all other diseases combined. They are rarely a direct cause of death, but they precede or incite many other serious infections, notably the bacterial pneumonias, subacute bacterial endocarditis, septicemia, purulent diseases of the accessory nasal sinuses and meningitis, and frequently precipitate the symptoms of peptic ulcer, coronary occlusion and other diverse diseases.

EPIDEMIOLOGY

In general, the epidemiology of component members of this group of diseases is similar. The causative agents are harbored in patients and in asymptomatic carriers who serve as migratory sources of infection. As the Wells have shown, secretions expelled as visible droplets by talking, sneezing or coughing are not so important in disseminating viruses from these sources as the minute, invisible, exhaled particles which float about in air like tobacco smoke. Other means of transfer undoubtedly exist also. Persons who inhale infectious agents suspended in air or acquire them otherwise react in different ways. Those who are immune or who are resistant by reason of an intact mucous membrane or other factors escape disease; those who are susceptible become infected. Epidemics are most common and most widespread in winter, but they occur in all seasons and in all climates (the Thomsons,[3] Smillie [2] and Hilding [4]). It is not known where the causative agents reside between epidemics, but viruses presumably are perpetuated by passage from person to person by a continuous chain of sporadic attacks or reside perennially in certain healthy carriers.[5] The incubation period and probably the carrier state are usually brief.

Little is known concerning specific immunity except in influenza. Immunity is believed not to last beyond several weeks or months after an attack.[6] Certain persons seem never to be attacked, while many have repeated bouts in a season. General resistance is thought to be afforded by good nutrition and health; yet robust persons in apparently excellent health contract infections. Local resistance appears to be largely dependent on an intact mucous membrane with its normal coating of mucus kept in motion by gravity and ciliary and muscular activity.[7] Lysozymes may also play a role. There is indirect evidence that chilling the surface of the body causes a reflex vasoconstriction and a fall of temperature of the mucous membrane favoring the invasion of viruses.[8] Mucosal irritants undoubtedly favor invasion, as shown by the mildness of experimental influenza in unanesthetized animals as compared with its severity when infection occurs during etherization, but the chief factor is the presence and activity of the causative viruses.

CLASSIFICATION

The group of infections of the respiratory tract are self-limiting diseases which have many epidemiologic, clinical and pathologic features in common. In the few studies available, the histologic changes of the nasal mucosa of the common cold [4] are almost identical with those of influenza in animals [9] and in man.[10]

In spite of many clinical similarities, if instances of infections are carefully studied individually or collectively, certain characteristics emerge which leave no doubt that a number of entities exist.[11] One may limit its attack to the nasal lining with profuse discharge (colds); one may cause sore throat (pharyngitis, tonsillitis); in one, constitutional symptoms predominate (grip); one is characterized by dry inflamed membranes with cough (viroid), and in another gastrointestinal symptoms may predominate (viral ? dysentery). Nevertheless, even in established entities clinical identification is obscured by variations in the susceptibility, immunity and reaction of the host to infection, which differences are reflected in various combinations of signs and symptoms and in the great variations of the severity of attacks in different persons and in the same person at different times. Differences also depend on the age group studied, on the general state of public health, on the season, on environmental circumstances and on other factors. In epidemics, attacks of all degrees of severity may be encountered ranging from subclinical infection or slight indisposition to severe

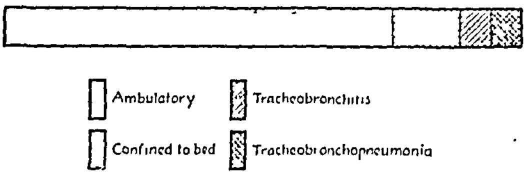
Read in the General Scientific Meetings at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 2, 1946.

Because of lack of space, this article is abbreviated in The Journal by omission of the footnotes and portions of the text. The complete article will appear in the author's reprints.

and even fatal, uncomplicated forms in which the whole respiratory tract may be affected (see the accompanying chart). Such variations may be accounted for by different reactions of different hosts to the same virus, and also to infection with a number of different viruses, some of them probably related, each of which causes disease characterized in general by a certain train of symptoms comprising an entity; yet there is so much overlapping as to defy clinical classification. The problem is, of course, further complicated when two or more different diseases concur in a community.



The relative proportions of mild and severe infections during an epidemic of "viroid" among 400 persons. Six per cent had pneumonia.[17]

field prepared by the viral infection, which indeed it may be. Yet there is ample evidence in diseases such as measles, vaccinia, lymphocytic choriomeningitis and influenza that a primary bacteria-free viral pneumonia occurs.[16] Although Reimann suggested in 1938 [11a] and later gave evidence [17] that viral pneumonia in certain epidemics represents only the severest form of an otherwise mild, widespread disease and is caused by the same agent, there has been a reluctance to accept this view partly from force of habit or tradition and partly because etiologic proof is absent. Subsequent reports [18] of similar observations add support to this concept. There is abundant epidemiologic, clinical and pathologic evidence of the viral cause of the pneumonic forms. Infection was transmitted by filtered washings from patients to volunteers in whom the disease developed with different degrees of severity, with and without pneumonia.[19] A newly isolated virus considered to cause about 60 per cent of attacks of viral pneumonia was isolated in 1944 by Eaton and his associates,[20] but studies on nonpneumonic forms have not yet been completed. If etiologic proof comes, it will be wrong to regard certain epidemic forms of viral pneumonia as a disease separate from the great preponderance of mild disease. To correct this defection, temporarily at least, the new name viroid was proposed [21] to cover all gradations of severity of the syndrome. The term if adopted should eventually be replaced by names for specific entities, as the causes are discovered.

Percentage of Symptoms and Signs in Various Infections of the Respiratory Tract

	A	B	C	D	E	F
Disease	Common cold	Exudative pharyngitis and/or tonsillitis	Grip "influenza"	Febrile catarrh	Viroid	Influenza A

Complications	Common	Rare	Common		Rare	

Confusion in classification arises also from the nature and site of predominant symptoms, depending largely on the multitropism of the virus. In the respiratory tract, symptoms and signs obviously arise from the local effects of the virus, and constitutional symptoms may be accounted for by the circulation of toxin made or liberated by the viruses, if analogy may be drawn with the evidence of toxins of influenza viruses given by the Henles.[12] Viruses which affect principally the upper part of the respiratory tract at times also appear to be neurotropic [13] and to cause encephalitis, as in some instances of viroid [14] and influenza, dermatotropic as in the exanthems, and pneumotropic or enterotropic, as disclosed in the following paragraphs.

Pneumonias.—Pneumonia occurs in a small percentage of most epidemic diseases of the respiratory tract, as shown in the accompanying table. The incidence of pulmonary involvement will be found to be even higher in minor diseases of the respiratory tract than is indicated in the table, if roentgenograms were made routinely.[15] Until recently the pneumonia was usually regarded as a different disease or a complication caused by the secondary invasion by pathogenic cocci of a

Gastrointestinal Disorder.—Gastrointestinal derangement in the form of anorexia, nausea and vomiting occurs in some patients with disease of the respiratory tract, as shown in the table. This occasional occurrence gave rise to the undesirable term intestinal influenza, when in reality the symptoms are incidental to a disease of the respiratory tract. However, for the past twenty-five years reports have appeared of widespread epidemic diseases in which symptoms of gastrointestinal disorder predominate over those arising from the respiratory tract; these diseases seem to be specific entities commonly called epidemic nausea, vomiting and diarrhea. Their epidemiologic similarity to viral diseases of the respiratory tract, together with suggestive evidence that they are caused by filtrable, air-borne agents and enter the respiratory tract where they occasionally give local symptoms, justifies their mention as viral dysentery in this discussion.[22]

Terminology.—Medical history reveals many attempts at nomenclature, nosography and classification. The ancient Greeks used the terms coryza and catarrh; the Romans, gravado.[23] Later, influenza, grip, *Schnupfen, Erkältung, rhume, romadizo, la monga,* the cold, sniffles and others were introduced. Rhinitis, nasopharyngitis, tonsillitis, pharyngitis, laryngitis, tracheitis and pneumonitis or pneumonia are used according to the anatomic area affected, either alone or in various clumsy combinations, logically even as nasopharyngolaryngotracheobronchopneumonia when all areas are involved at once or in sequence, as they may be.

Because of the mass of confusing and uncertain factors just discussed, little progress in classification may be expected until etiologic diagnoses are possible. The first steps in this direction were made by Kruse in 1914 and later by others, who showed that colds were caused by filtrable agents.[24] A virus was cultivated artificially by Dochez. The greatest advances were the discovery of the virus of influenza A in 1933 by Smith, Andrewes and Laidlaw and, later, of influenza B by Francis and Magill, establishing influenza as a group of at least two specific entities.

For the sake of convenience in discussion and for the provision of possible points for further attack, some sort of arrangement of the common infections of the respiratory tract is desirable. A tentative grouping based partly on clinical and epidemiologic grounds and, so far as is possible, on an etiologic basis is proposed in the table. The outstanding features of each disease are emphasized in heavy type, and the obvious overlapping of most features illustrates the hazards of clinical classification. A brief discussion of each disease follows.

A, The Common Cold.—The symptoms and signs of the common cold are too well known from general personal experience to be recited here. Adequate reviews of epidemiologic, clinical and etiologic studies are available.[24] While differentiation may be impossible at times, reflexive, allergic, vasomotor or irritative rhinitis[23] should not be included in the group of colds caused by viruses. The outstanding features of colds are their periodic occurrence throughout the world in widespread epidemics or in sporadic form, characterized chiefly by rhinitis, rhinorrhea, mild indisposition and occasional complications by pyogenic cocci as shown in column *A* of the table. While the features listed statistically differ considerably from those in other columns, the common cold may be indistinguishable from influenza,[25] grip [26] and viroid.[17]

There are no accurate statistics in regard to the incidence of nonbacterial pneumonia as part of the primary infection in epidemics of the common cold. During mass roentgenography,[15b] evidence of pulmonary invasion is present much oftener than such invasion is suspected clinically.

B, Pharyngitis and/or Tonsillitis.—Because of the predominance of sore throat and of severer constitutional symptoms in pharyngitis and/or tonsillitis, this group is set apart from the common cold. According to Abernethy's experiments,[27] diseases resembling the common cold and pharyngitis were transmitted as distinct diseases to volunteers with incubation periods of one to two and five to six days, respectively. Although in column *B* of the table sore throat is statistically the same as in certain other columns, its predominance as a sign and especially as a chief complaint sets this group apart from the rest (Townsend [24a] and Dingle [28]) excepting influenza.[10]

According to Dingle's group [28] and contrary to common opinion, hemolytic streptococci were probably the cause in only 25 per cent of cases, as shown by serologic evidence; they were present but probably not the cause in another 25 per cent, and in 50 per cent there was no evidence of their presence or activity. While infections caused by streptococci were more severe than those caused by a presumptive virus, it is not possible to diagnose the condition carelessly called a "strep. throat" by inspection or by clinical evidence alone.

C and D, Grip and Febrile Catarrh.[29]—These groups in general comprise syndromes which, prior to 1933, were called grip or influenza and included specific influenza and viroid. Many other viral diseases accompanied with aching, fever and a normal leukocyte count, if undiagnosed specifically, may be mistakenly called grip, as has occurred in an epidemic of yellow fever in Brazil, in mild poliomyelitis and in lymphocytic choriomeningitis. The endemic influenza of Horsfall,[30] which often occurs during epidemics of influenza A or B, but without cultural or serologic evidence of either, and the unusual epidemic of Oliphant and Dawber [31] may be included here for the present. These groups differ chiefly from the common cold by their greater severity or greater proportion of more severe attacks and by the prominence of fever and constitutional symptoms. There are few distinguishing clinical features among them or even when they are compared with columns *E* and *F*, in which some of them may actually belong. Cough, nasal obstruction, dry but not painful pharyngitis, conjunctival injection and constitutional symptoms are common to all.

E, Viroid.—The symptoms and signs listed in column *E* include both those of the nonpneumonic forms and of viral pneumonia which are regarded here as different degrees of severity of the same entity or syndrome. The relative proportion of mild, moderately severe and pneumonic forms in one epidemic is illustrated in the accompanying chart. The signs and symptoms are much like those of the diseases in columns *C*, *D* and *F*, making the infections clinically indistinguishable from each other. A striking difference of viroid, as also recorded in most reports of severe forms, is the rarity of pyogenic complications. Diagnosis of the mild forms may be tentatively made by the coexistence of pneumonic forms during an epidemic and the demonstration of a cold agglutinin in a variable proportion of the patients during convalescence. Serum from a number of patients with mild nonpneumonic attacks neutralized Eaton's virus. General information of the viral pneumonias is reviewed elsewhere.[32]

F, Influenza A and B.—Numerous reviews of influenza [33] make detailed discussion unnecessary here. Since the discovery of its cause, influenza is removed from the indeterminate group of infections of the respiratory tract and established as an entity to serve as a model or standard against which others may be compared. The term influenza should now be used only in its restricted sense for disease caused by the viruses of influenza A or B. It is uncertain what name to apply to identical and often coincidental disease in which the virus of influenza or serologic evidence of its presence cannot be shown. It has been called influenza X or Y and endemic influenza.[30] It may be a different entity or it may represent attacks of A and B virus without demonstrable evidence thereof.

Influenza is said to differ from other infections of the respiratory tract by favoring secondary pyogenic bacterial invasion, yet this characteristic is not evident in all outbreaks. It was especially operative in the 1918-1919 pandemic, presumably of influenza A in its severest form.[33c] The high mortality rate was chiefly due to pneumonia caused by pneumococci, hemolytic streptococci and staphylococci and by a shocklike state. In a small proportion of cases in man[34] and in most animals experimentally infected,[34a] the lungs are attacked by the virus.

As stated earlier[35] influenza is clinically indistinguishable from other viral infections of the respiratory tract. In Adams' epidemic[10] among children, pharyngitis was the most characteristic feature. Swab preparations of material removed from the inflamed pharynx contain sheets of sloughed-off epithelial cells and an exudate of mononuclear cells characteristic of influenza A and of other viral infections of the throat. Diagnosis can only be made by the isolation and identification of the viruses or the serologic evidence of their activity by the complement fixation test, the Hirst chicken erythrocyte agglutination test and later by the demonstration of specific protective antibodies. Unfortunately, these tests are not yet generally used in the average diagnostic laboratory. Etiologic diagnosis is essential for epidemiologic investigation and for the efficient use and evaluation of the specific prophylactic anti-influenza vaccines now available.

TREATMENT

Nothing can be done specifically to shorten attacks of the group of diseases in question; and, except for influenza, little can be done to prevent them. Yet in spite of advice to the contrary in most modern textbooks, the management of the common infections of the respiratory tract often resembles an unreasoning mental reflex of applying a standardized ritual of purging, sweating, poulticing, gargling, cough prescriptions and pills—treatment which is rarely given for similar symptoms in other disease. Whether or not the outlay of millions of dollars[36] on obsolete, illogical medicaments, largely brought about by commercial advertising and self medication should concern physicians, a critical appraisal of the problem is needed, not only to prevent waste and actual harm, but also to reduce the cost of medical care. In the paragraphs that follow a critical appraisal of some of the common therapeutic and preventive procedures precedes a commentary on rational treatment and preventive measures.

CRITICAL APPRAISAL

Chemotherapy and Antibiotic Therapy.—In spite of the ineffectiveness of the sulfonamide compounds[37] and of penicillin[38] in viral diseases, these agents continue to be wasted in huge amounts in the treatment of viral infections of respiratory tract. Nor are there any facts to justify their use routinely to prevent possible secondary bacterial invasion which occurs in the minority of cases. Penicillin is less objectionable than the sulfonamides because of its relative lack of harmful side effects, but both agents if used too widely over long periods may give rise to strains of drug-fast pathogenic bacteria resistant to treatment with either.

Diet.—The old adage "stuff a cold and starve a fever"[39] should be interpreted to mean that there is no reason for withholding food during a cold but fevers, of course, should not be "starved." Diet in otherwise well nourished patients is of little importance during the short period of uncomplicated sickness.

Elimination.—Tradition favors the stimulation of excretion by the bowels, the kidneys and the skin to abort disease or to "get rid of the poisons," but there is no evidence that either effect is accomplished. Purgation may be harmful; it is unnecessary and exhausting. The same can be said for diuresis with unreasonably large amounts of water. It is doubtful if most of the remedies, such as sodium citrate, solution of iron and ammonium acetate, or spirit of ethyl nitrite, often used as diuretics, are effective.

It is difficult to account for the continued use of diaphoretics in the form of heat, blankets, compound powder of ipecac,[37b] hot lemonade or the mustard foot bath, which only increase the discomfort in certain infections already characterized by sweating. Severe diaphoresis is exhausting. A degree of vasodilation and mild sweating may provide a sense of comfort in "dry" types of disease of the respiratory tract, but no specific benefit accrues.

Alkalinization.—Despite the exploitation of the dangers of acidosis during colds by mineral water and nostrum vendors, citrus fruit merchants and others it is doubtful if acidosis significant enough to require treatment ever occurs in otherwise normal patients. Many of the advertised remedies are pleasant to take, however, and many are expensive.

Antipyretics.—General opinion now holds that a moderate degree of fever is helpful in overcoming infections, yet acetophenetidin, acetanilid, quinine, aminopyrine and salicylate compounds are widely used as antipyretics. They comprise the chief ingredients of many so-called "break-up-a-cold" nostrums. They have no effect on the infectious process. A reduction of fever and a false feeling of improvement may be harmful in tempting the patient to resume his usual activity.[40] The toxic and therapeutically effective doses often have little margin between them, and unpleasant or toxic side effects occur. The additional analgesic effect of certain of these drugs in moderate dosage provides the only justification for their continued use.

Irradiation.—Aside from a pleasant sense of warmth from infra-red rays and the psychologic effect of ultraviolet light, neither has a specific beneficial effect.[41]

Counterirritants.—Counterirritants applied to the chest or throat in the form of cupping; poultices of flaxseed, onions, mud or bread; capsicum, methyl salicylate, turpentine, mustard, hot goose or bear fat, and many proprietary compounds are traditional remedies. They were used to "draw the blood from congested areas." They are not harmful if properly applied to avoid burns and provide a pleasant sense of warmth, keep the patient's mind from other discomfort and guarantee the concrete evidence of solicitousness which so many enjoy during a dejected state. The comfort they provide can be furnished more easily by a hot water bottle or electric heating pad.

Cough Remedies and Expectorants.—Most cough remedies are inheritances of folk-lore. Yet many patients expect or demand a "cough mixture" in medical practice, purchase one of the hundreds of brands sold commercially or make their own. Few other human discomforts are so widely exploited by commercial interests as coughing. Coughing serves a useful purpose and should not be checked unless it is harassing or exhausting. Cough medicines commonly contain demulcents, expectorants and supposed antiseptics and serve as unnecessary vehicles for sedatives and other drugs. The popularity of many elixirs and nostrums depends largely on the amount of alcohol they contain.

Syrup of wild cherry U. S. P., syrup of tolu U. S. P. and elixir of terpin hydrate N. F. are anachronistic vehicles. If codeine or other drugs are to be used, they are better given alone. Demulcents have little effect except in the oropharynx, since they are swallowed down the esophagus and inflammation is present in the nose, larynx or trachea.

Expectorants may be irritating and should not be used during the inflammatory stage or in infections in which exudate is naturally either minimal or profuse. Experiments show that potassium iodide, ammonium chloride or ammonium carbonate and creosote compounds do not change the volume or viscosity of the sputum.[12] They are slightly emetic, tend to increase the flow of saliva, not of exudates, and disturb digestion.

In spite of the demonstrated expectorant action in animals,[12c] one wonders if it is desirable or necessary to increase the output of fluid in the majority of cases of infection of the respiratory tract, especially during the febrile period, or whether the addition of nausea to the symptoms is helpful. According to experimental studies of Hamburger and Robertson,[43] the more fluid the exudate, the greater its penetration to the depths of the lung to which infection may be carried; the more viscid it is, the greater the ease of its expulsion.

Local Therapy.—The importance of the coating of mucus and of ciliary activity has been mentioned, yet attempts are often made during infection of the respiratory tract to "treat" all accessible inflamed areas with gargles, irrigations, sprays, packs and swabs. These are often composed of irritant antiseptics such as silver-protein compounds, silver nitrate, phenol, iodine and essential oils either alone or dispensed in a host of expensive prescriptions. They are used in spite of the fact that none can be effectively bactericidal or virucidal on muscosal surfaces without destroying the membrane as well. Even if they were effective, they are washed away a few seconds or minutes after their application by ciliary activity, the flow of exudate and gravity.[44] Strong solutions may cause harmful inflammation, destruction of tissue and cilia and a prolongation of disease.[45] Furthermore, antiseptics do not penetrate to the subepithelial tissue.[46]

Gargles cannot reach areas other than the mouth and oropharynx. Medicated irrigations or sprays remove protective mucus; they may spread infection and if applied with force may cause invasion of the sinuses. Packing or swabbing can reach only a few accessible areas; they may injure the membrane and induce bacteremia.[47] It must be admitted that at times these procedures afford a temporary sense of comfort, but there is no evidence that the course of the disease is otherwise favorably influenced.

The local application of sulfonamide compounds in any form is condemned as dangerous. Penicillin, tyrothricin and streptomycin are not virucidal, and their effect in rhinitis is negligible.[48] The local application of ultraviolet rays is ineffectual and the inhalation of chlorine has long since been abandoned. The continual use of oily preparations as spray or nose drops may lead to the development of lipoid-cell pneumonia.

Nasal Vasoconstrictors.—According to Kully,[49] about two hundred and forty preparations of nasal vasoconstrictors as nose drops, sprays, inhalants and ointments can be purchased. Their use decreases neither the severity nor the duration of attacks and in some instances may prolong acute rhinitis.[40a]

According to some rhinologists,[50] ephedrine by causing vasoconstriction removes the protective hyperemia, lowers the local resistance and thereby violates the usual principles of the treatment of acute inflammation. A secondary congestive effect may follow vasoconstriction. The possible effect on the blood pressure in hypertensive patients must also be considered.

Amphetamine causes the same effect and may give rise to habituation.[51] Atropine sulfate, a common component of "coryza tablets," is given to lessen secretions. It diminishes the output of the nasal, lacrimal and salivary glands but has no effect on an inflammatory exudate. It may cause unpleasant dryness, tachycardia, palpitation and other discomfort.

CRITIQUE OF CERTAIN PREVENTIVE MEASURES

General.—Diet: Although experimental evidence suggests that animals given diets deficient in vitamins are more susceptible to certain infections[52] there is little hope that optimal nutrition[53] or the addition of vitamins[54] to the food of persons taking an average good diet will aid in the prevention of infections of the respiratory tract, in spite of extensive advertising to the contrary. There is no "anti-infectious" vitamin.[55] There is no evidence that sun tanning or exposure to ultraviolet light prevents colds. Face masks as usually worn are of no value.

Hardening: The so-called hardening or habituation to changes in temperature or to fatigue is ineffective for the development of resistance to infection of the respiratory tract.[56]

"Cold" Vaccines: Since infections of the respiratory tract are apparently caused by a variety of viruses, most of which have not been isolated, there is obviously no specific prophylactic vaccine against infections due to any except influenza A and B.[57] Even influenza vaccines are not wholly satisfactory. The usual commercially prepared cold vaccines contain a mixture of bacteria which have nothing to do with colds, except perhaps as secondary invaders in a small percentage of cases. And even if they did, there is no acceptable evidence that vaccine prevents their invasion. Extensive controlled studies by Diehl and others have shown that cold vaccines whether given orally, parenterally or as a nasal spray do not prevent colds.[58] Gamma globulin is ineffective as a prophylactic agent.[59]

Tonsils and Adenoids.—According to Kaiser[60] and to Smiley,[61] colds occurred in children or adults equally whether or not their tonsils had been removed. Nor did tonsillectomy and adenoidectomy reduce the incidence of sinusitis, laryngitis or bronchitis. Obstructive adenoids, however, did appear to bear a relationship to frequent colds.[60]

It would seem from the preceding discussion that little of value is left for the treatment of this great group of diseases, which in a specific sense is true. Until the causes are discovered and specific therapy is developed, there is nothing available to prevent attacks, except of influenza, or to lessen the severity or shorten the duration of these infections. On the other hand, a number of procedures are recommended to lessen the discomfort of the patient, to provide for unimpeded natural recovery and to lessen the danger of complications.

RATIONAL THERAPY

Treatment should never be standardized but should be suited to the needs of each patient.

Rest.—Rest, as for any other infectious process, is the best treatment for acute disease of the respiratory tract, especially if fever is present, in which event confinement to bed is necessary.[40a] Rest and confinement serve several purposes: (*a*) to aid recuperation in itself, (*b*) to lessen complications, (*c*) to prevent the spread of the disease to others and (*d*) to avoid contact of the patient with carriers of pathogenic bacteria. It is common experience to observe, however, that in the mildest infections the discomfort therefrom is often less annoying if the usual occupation or other diversion is pursued.

Diet and Fluids.—Little attention need be paid to diet and fluids in the average uncomplicated, short infection as long as reasonable amounts are ingested. The amounts of both food and liquids may be suited to the patient's choice. In severe cases the caloric intake, the bulk of the diet and the amount of fluid must be regulated accordingly.

Elimination.—If the habitual function of the bowel is undisturbed nothing need be done.[49a] For constipation the diet should be adjusted, and mild laxatives or enemas may be used. For diarrhea, rest in bed, regulation of the diet and heat applied to the abdomen are effective. Camphorated tincture of opium U. S. P. may be helpful at times. Patients who sweat profusely should be kept in bed, kept dried and given a change of linen as often as necessary. Atropine sulfate in doses of 0.6 mg. (1/100 grain) may lessen sweating. Analgesic drugs which increase diaphoresis should not be given.

Certain patients, but not all, receive comfort from mild diaphoresis provided by hot drinks, a hot bath, acetylsalicylic acid, a mixture of codeine and papaverine hydrochloride[62] and beverages containing alcohol.

Analgesics.—Aching and headache are best controlled by warmth, rest in bed and the commonly used salicylate compounds, the amounts used being dependent on the relief afforded. The temporary symptomatic benefit does not terminate the infection. Drugs should not be given routinely but only if necessary. Because of the inherent dangers or the unpleasant side effects, acetophenetidin, acetanilid, aminopyrine and caffeine need not be used.

Insomnia or restlessness are lessened by mental ease, comfort, small amounts of alcohol, hot drinks, sodium bromide or barbiturate compounds given only as needed. Alcohol has been used for generations to abort impending colds or to treat them. Without doubt in reasonable doses it provides comfort, induces drowsiness and an appropriate desire to rest; it causes peripheral vasodilatation and reestablishes circulation in chilled cutaneous and mucosal surfaces.[63]

Antibiotic agents or sulfonamides are used only in the presence of suspected or known complications caused by bacteria susceptible to their effects.

RATIONAL LOCAL THERAPY

Nasal Obstruction and Rhinorrhea.—Even temporary relief from the discomfort of nasal obstruction and running nose justifies the use of vasoconstrictive drugs[64] like ephedrine, epinephrine, naphazoline hydrochloride and amphetamine despite the objections mentioned previously. They are most safely applied in the form of a dilute, gentle spray or in convenient inhalers (amphetamine, 2-aminoheptane), but each should be used minimally; that is, as seldom as possible, and only to the point of opening the airway. The unphysiologic principles involved in the resulting ischemia and the possible irritative effect, idiosyncrasy, the presence of hypertension and the danger of habituation must be considered.[64a] Certain patients obtain relief by the inhalation of volatilized menthol, camphor, volatile oils and resins or by exposure to the heat of an open fire or to infra-red light. In others, cold air offers more comfort.

Vasoconstriction by the means just mentioned often controls rhinorrhea so that atropine with its unpleasant effects is rarely needed. The opposite condition, or excessive dryness, is aided by humidifying and cooling the frequently overheated, desiccated indoor air in winter.[49a] Gentle spray of isotonic solution of sodium chloride into the nares is helpful. Solutions used intranasally are not irritating if their hydrogen ion concentration is nearly neutral, in a range between p_H 6.8 to 8.4.[7c,d] The nose should be blown gently and as seldom as possible through both nostrils at once into disposable tissue. Thorough drying and ointment applied to the nares prevents chapping. Lesions of incidental herpes simplex should be sponged frequently with 95 per cent alcohol; ointments should not be used.

Sore Throat.—The unphysiologic principles, the futile and possibly harmful effects of gargling or swabbing with medicated solutions hardly justifies their use for the transitory relief they afford. Little can be done safely for painful pharyngitis besides the use of general analgesics or narcotics, spraying with warm isotonic solution of sodium chloride or solutions containing mildly anesthetic agents like thymol (liquor antisepticus, N. F.), or the application of heat to the throat. The application of cocaine solution is subject to the dangers of idiosyncrasy and habituation.

Demulcents like slippery elm, glycyrrhiza or glycerin in single swallowed doses exert a brief soothing effect. For a continual effect, they are better applied as lozenges dissolved in the mouth, so long as the digestion is not disturbed.

Cough.—A degree of coughing may be desirable and needs no treatment in the majority of patients, except when its frequency must be lessened somewhat to permit sleep and when its severity is painful, exhausting or dangerous. Treatment depends on whether the cough is caused by irritation from inflammation or dryness in the upper passages or from the collection of exudate lower in the respiratory tract. Coughing is often unnecessary and habitual. It can be voluntarily restrained if attention is directed to the fact, and there is no advantage in struggling to raise exudate which would be resorbed naturally. When cough is due to dry irritation, cooling and humidification of the air with elaborate systems or cheaply with water vaporizers is helpful. Inhalation of steam, with or without nonirritating aromatics (benzoin, camphor, menthol or eucalyptol) or spraying with isotonic solution of sodium chloride is helpful. The same result may be accomplished with slowly dissolving aromatic lozenges. A cloth binder (not adhesive tape) applied to the lower part of the chest and upper part of the abdomen gives a sense of comfort and support and relieves the soreness of the muscles. In some cases, 0.5 cc. of 0.5 per cent solution of *p*-chlorophenol in liquid petrolatum sprayed into the larynx or trachea with a curved-tip syringe gives relief for several hours. The substance has an anesthetic effect but is irritative.

Patients should restrict the use of their voice during the inflammatory stage of the infection. Smoking is generally contraindicated.

In infections with profuse secretion, coughing is helpful. So-called expectorant drugs have little or no effect on the tenacity of the exudate and often derange the digestion. Perhaps the best physiologic expectorant is carbon dioxide[65] which if inhaled in 5 or 10 per cent concentration with oxygen increases the depth and rate of respiration, increases muscular and ciliary activity and aids in the expulsion of exudate.

Codeine in doses of 5 to 10 mg. is the drug of choice for quieting overactive cough reflex.[66] Larger amounts may increase irritability. It should be given in tablet form, not in sweetened vehicles. For extremely severe persistent or paroxysmal cough, morphine may be used as a last resort. Diacetylmorphine is too depressive and may cause addiction.

Treatment of the Severe Pneumonic Forms of Infection.[32b]—The symptomatic treatment of the severe pneumonic forms of infection is essentially the same as that previously described. Dyspnea and cyanosis improve with oxygen therapy. Circulatory failure requires appropriate supportive management.[66a] The question of specific therapy with sulfonamides or with antibiotics often arises. They need not be given unless it is certain or reasonably certain that infection with drug-sensitive bacteria exists. There is no acceptable evidence of the beneficial therapeutic effect of either roentgen therapy or convalescent serum. Convalescence of one to two weeks is desirable.

RATIONAL PREVENTIVE MEASURES

General.—Instruction of the public in regard to the fallacies or benefits of various prophylactic measures is perhaps the most important measure. Public opinion may eventually oblige the ambulatory patient to isolate himself voluntarily during the contagious period, and persons especially susceptible to infections may learn to avoid the proximity of those who are ill or of crowds when colds are prevalent. Patients should learn to restrain coughing, sneezing and kissing. Nasal exudates and sputum should be deposited in tissue paper and burned. There are no practical means by which the asymptomatic carrier may be detected. Strict isolation could prevent infection in noncarriers, but it is seldom possible. Isolated communities often pass through a winter without colds until infection is introduced by visitors.[66b]

Although excellent physical condition, peace of mind, adequate diet and pleasant weather supposedly furnish resistance, infections of the respiratory tract occur for no obvious reason in otherwise robust persons. However, certain circumstances known by common experience to lead to colds such as exposure to wet and cold, sudden chilling in drafts, volatile irritants, dust, fatigue and other excesses should be guarded against, or neutralized by rest, warmth and comfort.[66c] Reasonably comfortable temperature and humidity of air in rooms is desirable, but no evidence is available as yet of their specific value. Residence in a climate where colds are less frequent is recommended for those who are subject to frequent infections, if economic circumstances permit.

New methods of sterilizing the air of closed quarters give promise of success. Volatilized propylene glycol in high dilution reduces the incidence of colds in controlled groups of persons[67] providing they do not leave the sterilized atmosphere. The same result has been noted for air irradiated with ultraviolet light, but recent experience[68] shows that it is not always effective.

Vaccines.—Except for influenza, no specific prophylactic vaccines exist.[69]

Local Measures.—As indicated previously the mucous coating and ciliary activity are perhaps the best barriers to infection. No measures should be used which disturb them. Mechanical obstruction of the nose by polyps or adenoids should be corrected surgically. Unless the nasal septum is extremely deviated, it should not be "straightened."

SUMMARY

The common infections of the respiratory tract of viral or presumably viral origin can be tentatively grouped on epidemiologic, clinical and etiologic grounds as the common cold, pharyngitis, grip, viroid and influenza. The causes of some are known and those of the rest await discovery before final classification is possible. Many preventive and therapeutic measures in common use are in need of revision or deletion. Except for influenza there are no specific preventive procedures, and no specific therapy exists for any infection of the group. Management should be suited to the needs of the patient in order to relieve discomfort, to prevent complications without impeding the natural process of recovery and to minimize the spread of infection to others.

LEUKOPLAKIA (LEUKOKERATOSIS) OF THE PALATE, PAPULAR FORM

Its Relation to the Use of Tobacco

Chairman's Address

CLYDE L. CUMMER, M.D.
Cleveland

Much has been written concerning leukoplakia buccalis, but references to its occurrence on the palate are scanty. Moderate diffuse grayness in this area is not an unusual observation, and plaques similar to those on the mucosa of the cheeks are mentioned occasionally. However, the first appearance of the papular eruption of palatal leukoplakia in the American medical literature was in an article by Fordyce and MacKee[1] published in 1926. Without elaboration in the text, there was a photograph which portrayed a condition that the legend designated as "mucous adenomas of the palate." Under the title "pseudoleukokeratosis of the buccal mucous membranes" Grütz[2] described 3 cases in 1928. In the succeeding year Howard Fox[3] presented a patient at a dermatologic meeting as having "gray rugae of the hard palate." From the description I infer that this was an example of the same disease. In 1930 Harold Orr[4] reported 7 cases of a "peculiar papular eruption of the hard palate" and described the histologic observations. Since then reports have been added by Hückels,[5] Krainz and Kumer,[6] Ronchese,[7] Tappeiner,[8] Thoma[9] and Cahn.[10] Photographs with-

---

Read before the Section on Dermatology and Syphilology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

Acknowledgment is made of the assistance of Dr. Howard T. Karsner in the preparation of the photomicrographs and of Dr. Donald J. Rehbock in the histologic studies. Dr. George Miller MacKee furnished the photograph of the patient whose case was originally reported by Fordyce and MacKee.[1] Dr. Charles G. LaRocco cooperated in the clinical observations at St. Vincent Charity Hospital.

out clinical description are found in an article by McCarthy[11] and in Burket's[12] text (table 1). An excellent general description is given by Hayes Martin.[13] The condition has been referred to as papilliform leukoplakia, smoker's keratosis of the palate, smoker's palate, tobacco-conditioned leukokeratosis of the palate and stomatitis nicotina, as well as by the terms already mentioned.

SYMPTOMS

Subjective symptoms are slight or absent. Only occasionally does the patient perceive any roughness of the palate with the tip of the tongue, and the majority are unaware of the disease until it is discovered by examination. The appearance is characteristic. The notes I made at the time when Fordyce and MacKee's[1] patient, a white man aged 54, was first seen in Dr. Fordyce's office showed that the anterior third of the hard palate was almost covered by numerous closely aggregated small gray papules, pinhead in size, with slightly roughened surfaces. The posterior third of the hard palate and the entire soft palate were covered with bright red papules of similar size, which were equally closely set but had more hemispheric tops and were less firm in consistency (fig. 1). A water color drawing made at the time and still in my possession shows these characteristics clearly.

Table 1.—*Cases Reported in the Literature*

Observers	Sex			Ages	Use of Tobacco
	Male	Female	Not Stated

Totals	49	2	2		

With certain variations this description would apply to the majority of recorded cases. The entire palate is not always involved, nor are the papules inevitably small, for some as large as 5 mm. have been observed (fig. 2). The eruption appears more frequently on the hard palate than on the soft palate. Krainz and Kumer[6] noted a sharp line of demarcation between the involved and uninvolved portions of the hard palate in some instances but not in others. The mucosal surface intervening between the gray papules, although usually gray, may be fairly normal in appearance. Grütz[2] found that the white and thickened mucous membranes appeared as superficial cross folds, while Krainz and Kumer[6] described lengthwise and crosswise folds in 2 of their patients. When the papules are situated on the rugae there is a suggestion of gray bands crossing the anterior portion of the hard palate.

The prominence of the rugae exposes them to irritation. To determine the nature of their structure longitudinal sections were cut as shown in figure 3. They showed that the epithelial layer is the same in the elevated and depressed areas and that the elevations are due to pads of connective tissue beneath the rugae (fig. 4). In edentulous mouths the rugae are either entirely absent or greatly flattened.

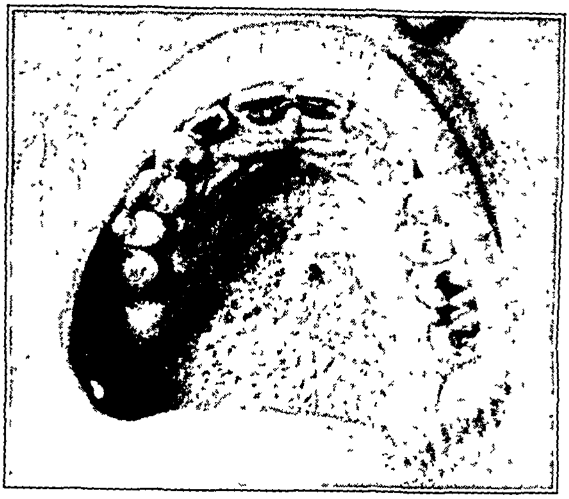

Fig. 1.—Papular leukoplakia. Original case of Fordyce and MacKee[1] Depression in center of hard palate is site of biopsy.

The striking and characteristic feature of papular leukoplakia is the occurrence of red dots, often with depressed or umbilicated centers, which cap some of the papules. These are observed only on the mesial-posterior portion of the hard palate and the soft palate. In this region Hückels[5] stated that the palatine mucous glands are situated, isolated at first and arranged in lengthwise rows further back. He quoted von Szontagh as having counted two hundred and fifty such glands on the hard palate of 1 person.

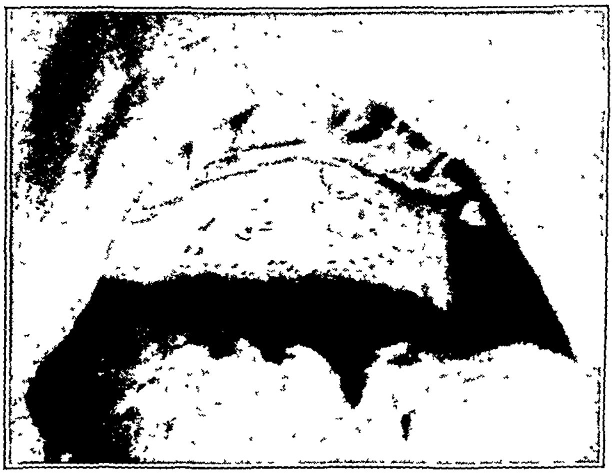

Fig. 2.—Papular leukoplakia, case 6. The papules are larger.

To confirm this statement and to plot the exact location of the palatine glands, palates were secured at autopsy and sections cut crosswise at regular intervals. Their distribution, which did not seem to vary with the age of the persons, is shown diagrammatically in figure 3. It should be observed that the central-posterior area in which they are situated is the only part of the hard palate in which red papules are found. They are also observed in many cases on the soft palate, which contains many mucous glands.

FREQUENCY OF OCCURRENCE

Eichenlaub's[14] study is of value in ascertaining the frequency of palatal leukoplakia. In examining 16,802 veterans at the Veterans Administration Facility in Washington, D. C., he found 327 persons with leukoplakia, with involvement of palatal and buccal mucosa in 3 instances and of the palate alone in 2. It is my opinion that the condition is frequently overlooked in routine examination and that it would be found much oftener if the palate were scrutinized in all cases. After discovering their first case accidentally, Krainz and Kumer[6] collected 9 more in a few months. Obviously the true nature of the lesions was not recognized even in some of the earlier cases reported by competent observers because of lack of familiarity with the clinical picture. Doubtless this accounts for the paucity of references in the American literature, to which Krainz and Kumer[6] have called attention. In this country dentists seem to have been more alert in the recognition of this disease than have the medical practitioners. To determine its approximate frequency in dermatologic practice I examined 587 palates with the results shown in table 2.

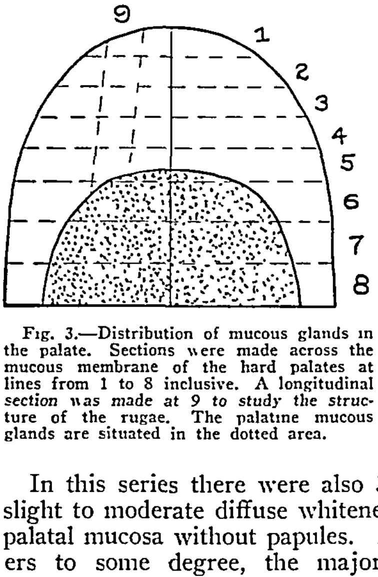

Fig. 3.—Distribution of mucous glands in the palate. Sections were made across the mucous membrane of the hard palates at lines from 1 to 8 inclusive. A longitudinal section was made at *9* to study the structure of the rugae. The palatine mucous glands are situated in the dotted area.

The number examined cannot be regarded as other than a sampling, but the table indicates that about 1 person in every 100 displays this condition, and the incidence is greatest in the later decades.

In this series there were also 33 persons exhibiting slight to moderate diffuse whiteness or grayness of the palatal mucosa without papules. All but 1 were smokers to some degree, the majority cigaret smokers. Their ages ranged from 17 to 71 years.

REPORT OF CASES

Case 1.—G. F., a white man aged 70, was a heavy pipe smoker. Flat-topped gray papules and rounded papules with red dots were seen on the hard and on the soft palate; there was no denture. A biopsy was made.

Case 2.—J. G., a white man aged 64, smoked fifteen to twenty pipesful of tobacco daily. He exhibited papular gray lesions, almost verrucous, with red dotted papules; also, a red, velvety appearance of the soft palate was observed. There was no denture.

Case 3.—T. M., a white man aged 47, smoked 1 to 1¼ ounces of tobacco in a pipe each day. Gray papules over the rugae on the anterior portion of the hard palate, along with grayness and red points on the soft palate were observed. There was no denture.

Case 4.—J. O., a white man aged 64, was a heavy pipe and cigar smoker. Gray papules and diffuse grayness of the entire palate, as well as the usual characteristic red points were observed. Buccal leukoplakia was also evident. There was no denture.

Case 5.—A. S., a white man aged 62, smoked four or five pipesful of tobacco daily and exhibited a patch about 1.5 cm. in diameter in the central portion of the posterior third of the hard palate, with gray flat-topped papules and also with papules which had umbilicated red centers. There was no denture.

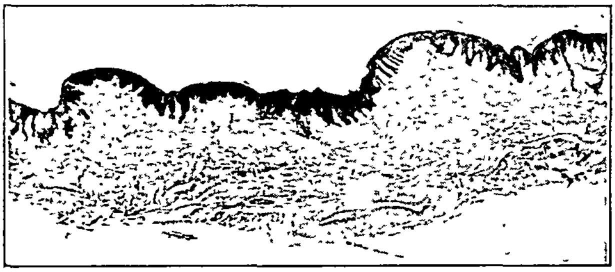

Fig. 4.—Longitudinal section through the anterior portion of the mucous membrane of the hard palate at *line 9* as indicated in *figure 3*. The elevations of the rugae are made up of connective tissue. There are no mucous glands in this area (× 7.4).

Case 6.—W. P., a white man aged 71 who smoked three small cans of tobacco a week, exhibited definite involvement of the palate with many flat-topped gray papules and umbilicated red topped papules on the middle and posterior thirds of the palate. There was no denture; a biopsy was made.

In addition I am permitted to report a case presented by Dr. Benjamin Levine of Cleveland at a meeting of the Cleveland Dermatological Society with the provisional diagnosis of angiokeratoma.

S. H., a white man aged 55, had a score or more of hyperkeratotic papillary lesions of the hard palate. In the center of each was a small bright red area, whereas the rest of the lesion was white. There had been considerable pain at times. A biopsy was made. The Kline test was negative. This man was a heavy pipe smoker.

HISTOPATHOLOGIC OBSERVATIONS

Histologically the essential observations include thickening of the epithelium with hyperkeratosis and dyskeratosis (fig. 5). Elongation and thickening of the rete pegs was usual. While Orr,[4] the first to describe the histologic changes in this disease, stated that there were no inflammatory changes in the dermis, Krainz and Kumer[6] observed slight changes in the cutis together with a moderate degree of perivascular infiltration of round cells and leukocytes; Ronchese[7] observed a small amount of fibrous stroma containing leukocytes, and Kurt Thoma,[9] round cell inflammation of the corium. Fordyce's case[1] showed considerable round cell infiltration.

Table 2.—*Frequency of Leukoplakia in Dermatologic Practice*

Age Groups, Years	Number Examined		Number with Papular Leukoplakia of Palate	
	Men	Women	Men	Women
10-19	22	38	0	0
20-29	72	79	0	0
30-39	47	61	0	0
40-49	61	53	1	0
50-59	60	25	0	0
60-69	33	12	3	0
70-79	16	3	2	0
80-89	4	1	0	0
Totals	315	272	6	0

Adequate study can be made only in serial sections; biopsies of my cases revealed dense infiltration of lymphocytes and polymorphonuclear leukocytes in the corium and decided dilatation of the capillary spaces in the papillary bodies immediately adjacent to the narrowed ducts of the palatine glands (figs. 6 and 7). It is possible that these enlarged capillary spaces filled with erythrocytes give to the rounded papules the bright red color which characterizes them, but Rehbock has suggested that the red color is reflected by the minute dots, possibly composed of mucin, at the orifices of the ducts.

---

[14] Eichenlaub, F. J.: Leukoplakia Buccalis, Arch. Dermat. & Syph. 37: 590-596 (April) 1938.

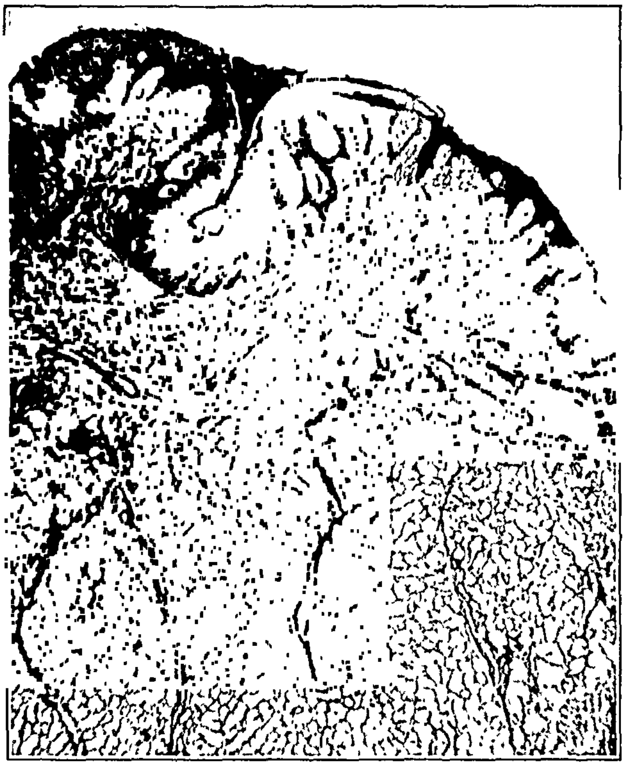

Fig. 5.—Biopsy in Fordyce and MacKee's[1] case, shown in figure 1. *Note hyperkeratosis and, in corium, cellular infiltrate* (× 30).

Krainz and Kumer[6] stated that the red spots seen microscopically appeared in section as moderately widened outlets of the mucous glands due to narrowing of the orifices by the horny layer and a resultant depression, while Cahn[10] in serial sections found that the leukokeratotic epithelium had broken in the center of the red papules to expose the corium. He felt that the red spot was not the orifice of the gland because both the red center and the orifices of the glands become occluded by keratinized epithelial cells. In sections studied by me the epidermis completely occluded the external orifice of the gland, the portion of the duct included within the specimen showed no dilatation or cystic change, and there was no adenomatous change.

Not long after seeing Fordyce and MacKee's case[1] I found that the condition was not adenomatous by comparing the sections from their case with sections of tissue removed from a corresponding location in a series of about 20 apparently normal palates. Cahn[10] stated that his sections showed no adenomas.

ETIOLOGY

Age and Sex.—Papular leukoplakia of the palate occurs predominantly in men. Of 53 cases, including 46 collected from the literature and the 6 observed by me, the sex is stated in 51, of which 49 occurred in men and 2 in women.

Orr[4] stated that his 7 patients were all over 40 years of age except for 1, aged 30. Fox's[3] patient was only 33; Cahn[10] had 1 aged 40; 1 of mine was 47, and in all the other cases reported, the ages ranged from 50 to 77.

Tobacco.—A history of tobacco smoking was obtained in all patients except 1 of Cahn's,[10] by whom it was denied; another of his, who made no statement, and 1 of Ronchese's[7] by whom smoking was denied. The descriptive terms adopted by many authors clearly indicated their opinions as to the causation of the condition. Pipe smoking was incriminated more often than cigar or cigaret smoking.

Additional evidence of the role of smoking was adduced by Krainz and Kumer,[6] who, in a 67 year old man, previously a nonsmoker, produced a gray-white color of the palatal mucosa with characteristic red spots by having him smoke a pipe excessively. Equally convincing evidence was found by Tappeiner[8] and by Thoma,[9] whose patients exhibited the lesions on the part of the palate not protected by a partial denture, although none were evident under the denture.

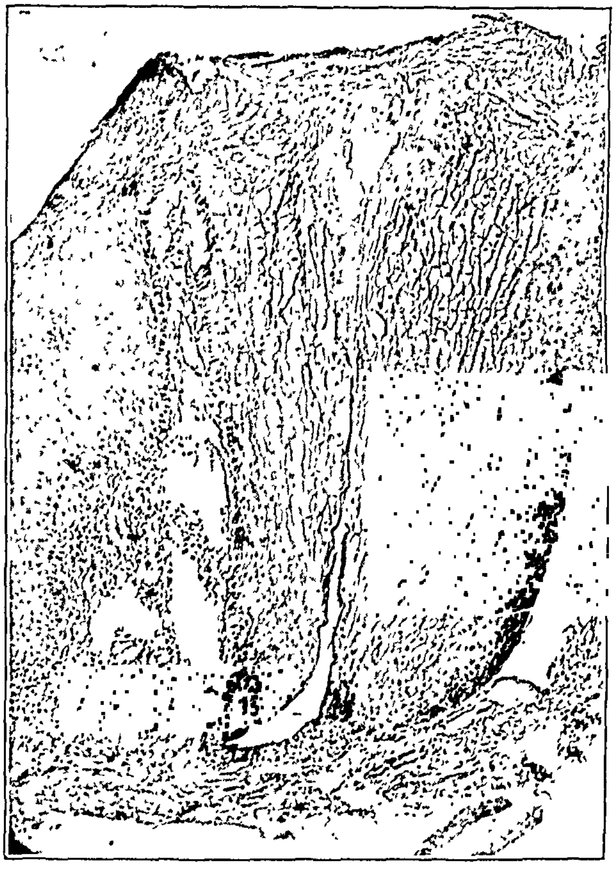

Fig. 6.—Section made as one of serial sections. Hyperkeratosis blocks the distal portion of the gland duct and flattens the epithelial cells lining the duct; there is a cellular infiltrate in the papillary body adjacent to the duct (× 74).

Vaughan[14a] was able to clear up palatal leukoplakia by having his patient wear vulcanite plates.

The effect of abstinence from tobacco is significant. Grütz[2] found that the lesions disappeared when pipe

---

14a. Vaughan, H. C.: Leukoplakia, J. Am. Dent. A. 22:65 (Jan.) 1935.

smoking was stopped and smoking otherwise was restricted. In Orr's[4] experience the only measure which resulted in cure was cessation of smoking. Two of his patients were syphilitics, 1 of whom stopped smoking with the resultant disappearance of the lesions in the course of four months. The other continued to smoke, and the lesions remained unchanged at the end of a year. According to Hückels[5] the prognosis was good when smoking was stopped. Thoma[9] also observed improvement in his patients after smoking had been discontinued.

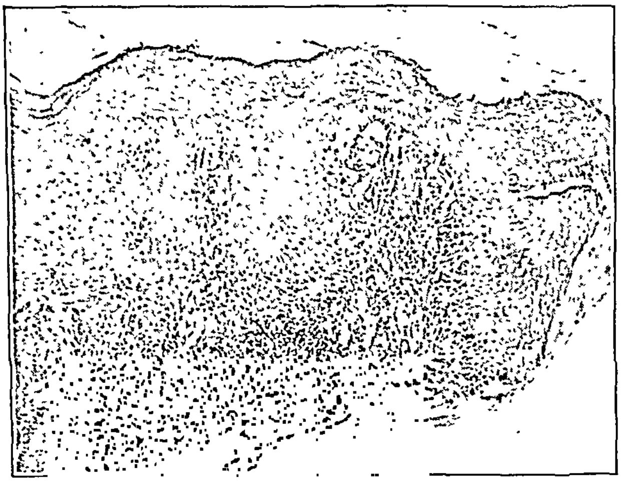

Fig. 7.—Section from same case. Hyperkeratosis, capillary enlargement and cellular infiltrate (× 67).

In this connection it might be well to consider briefly the opinions of some of those who have reviewed the general subject of leukoplakia of the mouth and its relationship to tobacco. Bettman[15] asserted that he had never seen leukoplakia in a nonsmoker. King and Hamilton[16] found that 69 out of 80 patients used tobacco in some form. Sturgis and Lund[17] stated that most authors agree in the observation that tobacco is used by 80 to 95 per cent of the patients with leukoplakia. In Eichenlaub's[14] 327 cases of leukoplakia, tobacco had been used by all the patients except 5.

The type of smoking is important. McCarthy[11] expressed his conviction that the pipe is the most irritating agent and emphasized the importance of the method of smoking in the localization of leukoplakia. It is suggested that pipe smoking is especially likely to produce palatal changes since the stream of hot and unfiltered smoke is delivered directly against the roof of the mouth, whereas cigaret and cigar smoke is to some extent filtered through the stub or butt and is diffused through the entire oral cavity.

Hayes Martin[13] seldom found mucous membrane changes in the soft palate "except in heavy cigar smokers (those who smoke fifteen to twenty a day) in whom the soft palate and the base of the tongue become deep red and congested with marked hypertrophy of lymphoid tissue. Cancer . . . associated with heavy cigar smoking (an expensive habit) has been termed 'rich man's cancer.'"

There are frequent references to Roffo's[18] experiments in which buccal leukoplakia was produced in rabbits by daily exposure to tobacco smoke. However, Bogen and Loomis,[19] who carried out experiments with mice and rabbits, made cutaneous application of the tar derived from the destructive distillation of tobacco, and treated controls similarly with coal tar of known carcinogenic properties. While the malignant change was observed in the controls, none resulted from the application of tobacco tar. The authors themselves pointed out that these results do not controvert the prevailing although not unanimous clinical observation that cancer of the mouth is unduly prevalent among those who are accustomed to the use of tobacco, since other factors such as mechanical irritation and the temperature of the smoke are involved.

Syphilis.—Formerly syphilis was considered prominent in the causation of leukoplakia. There has been a trend away from this concept in recent years, except possibly in regard to leukoplakia of the tongue. For example, Quick[20] has stated that it is misleading to associate leukoplakia with tertiary syphilis, and that there is probably more leukoplakia of nonsyphilitic than of syphilitic origin.

The relationship of syphilis in the reported cases of palatal papular leukoplakia appears to be slight. Only 2 of Orr's[4] 7 cases, 1 of Hückels's[5] 12 cases and 1 of Tappeiner's[8] cases were mentioned as disclosing evidence of syphilis either in the patients' history or in the results of laboratory examination. Tappeiner's case was significant because the patient was an old syphilitic with positive serologic examinations, but the lesions were seen only on the portion of the palate not protected by a denture.

TREATMENT

The indications for treatment are apparent. Cessation of smoking, especially pipe smoking, has resulted in either improvement or cure in too many cases to be disregarded. The wearing of a denture to protect the palate might be indicated in the case of inveterate, confirmed smokers.

Since the present vogue is to regard all human ills as deficiency diseases, it is inevitable that leukoplakia should be attributed to vitamin deficiency, the lack of both vitamin A and vitamin B having been incriminated. No convincing report of the beneficial effect of the administration of vitamin A has been found, but Abels, Rekers, Martin and Rhoads,[21] in an article accompanied by illustrations, have referred to results obtained by the use of either yeast alone or yeast with iron and hydrochloric acid. Of 23 patients so treated, 4 obtained the disappearance of all or a large part of the leukoplakic lesions on lips, tongue or buccal mucosa, while in 7 others the lesions became thinner or lost some of their yellow-white appearance.

PROGNOSIS

The prognosis in papular leukoplakia of the palate is good as far as may be judged from the small amount of clinical material on record. This has been especially true when smoking was discontinued. In none of

Hückels's[5] 12 cases did cancer develop, although all the patients were over 50 years of age. In his study of tumors of the palate, Hayes Martin[13] expressed his belief that while the larger lesions in palatal leukoplakia usually show papillomatous overgrowth of the epithelium and are common in pipe smokers, such changes are rarely associated with cancer, and there is little statistical evidence to indicate that they have any great importance from the standpoint of carcinogenesis.

SUMMARY

The manifestations of leukoplakia on the palate are not always similar to those on the tongue or buccal mucosa.

Papular leukoplakia of the palate has not been generally recognized in this country, and some of the earlier cases were reported under other diagnoses.

Undoubtedly the condition would be observed oftener if routine examinations of the palate were made, and it would be recognized more frequently if physicians and dentists were familiar with this clinical variant of leukoplakia.

The papular form presents a striking clinical picture. In this form there are gray flat-topped papules or red hemispheric papules.

The histologic observations include thickening of the epithelium with hyperkeratosis and dyskeratosis; elongation and thickening of the rete pegs, usually accompanied with capillary enlargement in the papillary bodies, and a moderate degree of inflammatory change in the dermis.

Practically all reported instances have been in men, almost all of whom have been smokers, especially pipe smokers. Syphilis does not seem to be a causative factor.

The condition has been cleared up in some cases merely by abstaining from smoking, while in others a protective denture covering the palate has been effective.

The prognosis is good, since in none of the relatively small number of recorded cases has malignant change developed.

The Tendon Fascicle.—The unit of tendon structure is the tendon fascicle. This consists of closely packed collagen fibers with their parent cells, the fascicles being bound together by a layer of fine connective tissue, the interfascicular tissue or endotenon. The cross sectional area of the fascicle is variable but lies within certain limits (0.125-0.375 sq. mm.). The interfascicular tissue is probably largely nutritional in function, and the characteristic limits to the area of the fascicle is probably related to nutritional requirements. The interfascicular tissue may also be compared with the packing of a laminated spring and facilitates internal movement of the tendon. Where it has no synovial sheath the tendon is surrounded by loose fatty areolar tissue, the paratenon, which fills the interstices of the fascial compartment in which the tendon is situated. In the simplest form of musculotendinous junction the muscle fibers are continued as collagen bundles, and each group of muscle fibers enclosed in perimysium continues as a tendon fascicle, the perimysium being continuous with the interfascicular tissue. Where the muscle fibers join the tendon obliquely this arrangement does not always hold, but there is a close correspondence between the grouping into bundles of muscle fibers and the grouping into tendon fascicles. At its insertion, the tendon becomes intimately connected with the bone and periosteum. The majority of the collagen fibers of the tendon are continued into the bone as the perforating fibers of Sharpey, and the interfascicular tissue becomes continuous with the periosteum.—Edwards, D. A. W.: The Blood Supply and Lymphatic Drainage of Tendone, *Journal of Anatomy*, July 1946.

MANAGEMENT OF PATIENTS WITH CHRONIC HEADACHE

ARNOLD P. FRIEDMAN, M.D.
CHARLES BRENNER, M.D.
and
H. HOUSTON MERRITT, M.D.
New York

Patients with chronic headache represent a considerable problem to the practitioner both because of their numbers and because of the stubbornness with which their symptoms often persist despite every effort at treatment. It is our purpose in this paper to outline some principles in the study and care of such patients which will help to achieve the best therapeutic results.

The great majority of all patients with chronic headache fall into one of the three following groups: migrainous, post-traumatic or psychogenic. The first two need no further definition here. In the third group we include patients whose headaches are found to be related to emotional stress, the relationship being seen either at once or after some study. These patients are without evidence of any organic disease which might be causally related to the headaches. They are chiefly women who have usually had headaches for many years, of either the acute, recurrent or the continuous, chronic type. The location and character of the headaches are variable, and there may be premonitory symptoms, such as photophobia, nausea or dimness of vision. In nearly all the women patients, the headaches are worse before or during menses.

The mechanism of all three of these types of headache is probably vascular. In the case of migraine, the pain is considered to be caused by paroxysmal dilatation chiefly of the intracranial branches of the external carotid artery. We have discussed the mechanism of post-traumatic and psychogenic headache in earlier papers[1] and have suggested that it may be similar to that of the headache which can be produced experimentally by the intravenous injection of a small amount of histamine, that is, to stimulation of the pain-sensitive structures in or near the walls of the large intracranial arteries by forcible vasodilatation. We wish to emphasize that there is no evidence at present that either of these two types of headache is caused by histamine sensitivity or by any other disorder of histamine metabolism.

Regardless of the precise mechanism of the production of pain in these three disorders, there is abundant clinical experience to prove that all three types of headache are readily precipitated and made worse by emotional stress and inner conflicts. It is of the greatest importance to bear in mind this apparent but often neglected fact when one is first examining and later treating a patient with chronic headache. If any one fails to do so, he must pay the price of his neglect ultimately in the form of less satisfactory therapeutic results.

Every patient with chronic headache should, of course, be given a thorough physical and neurologic

H.: Experimental Evidence of the Physiologic Mechanism of Certain Types of Headache, Arch. Neurol. & Psychiat. **54**: 385 (Nov.-Dec.) 1945.

examination. In our clinic roentgenologic examination of the skull and electroencephalograms are also routine; certainly these and other laboratory studies should be done whenever indicated. However, it is just as important, in accordance with what we have said in the preceding paragraph, that the patient be studied adequately from a psychiatric point of view. Chronic headache is truly a psychosomatic problem, and neither the psychologic nor the physical aspect can be neglected with impunity. The initial interview in which the patient's history is obtained is the time to begin the psychiatric examination and a detailed account of the present illness is of the utmost importance. Only by inquiring into the precise circumstances of the patient's illness can one learn, for example, that a 60 year old patient had her first headache at precisely the moment of her reconciliation with her elderly husband who had acquired a mistress while the patient was away from home visiting a married daughter.

Attention should be paid both to the subject organization, which gives a cross section of the patient's present difficulty, and to the personality organization and past history, which give a longitudinal section of the life of the patient and an indication of his adaptation to past difficulties. The examiner should be on the alert to determine what factors in the patient's inner life and environment precipitate the headaches and, if possible, to form an opinion as to the dynamics which are involved. On the basis of such a psychosomatic study, a diagnosis can usually be reached and a decision made as to further treatment.

A word of warning might be added here against diagnosing a headache as psychogenic purely on the basis of the patient's description of the distribution and character of the pain. The fallacy of assuming that a headache is psychogenic simply because it is described as a pressure sensation or as being viselike or of hat band distribution is illustrated by the following case.

REPORT OF A CASE

CASE 1.—A. O., a white female nurse, age 22 years, had been suffering from headaches for two months. These were described as consisting of a feeling of pressure throughout the head or in one or another part of it. They were occasionally accompanied by nausea or even vomiting and were usually relieved by acetylsalicylic acid. Two days before entry into the hospital, the headache grew worse, and the patient felt tired and listless. During the recent, severe headaches, the patient screamed at times, was emotionally upset and even seemed confused but if she was spoken to she could always be roused and brought into contact. When the history was taken it was learned that she was dissatisfied with her present job, and that she had left her previous, congenial one just before the onset of her headaches. She lived with her family and was under considerable emotional tension, both because she disliked her stepfather and because the other members of her family disapproved of her fiancé.

Physical and neurologic examinations were negative except for questionable blurring of the disk margins. Roentgenograms of the skull and lumbar puncture did not reveal any abnormality. An electroencephalogram was diffusely abnormal, more on the left than on the right. Since visual field studies showed enlargement of the blind spots, a pneumoencephalogram was attempted, but the ventricles failed to fill. A ventriculogram then revealed dilatation of the entire ventricular system, and at operation a medulloblastoma was removed from the left cerebellar hemisphere.

As a diagnostic aid in the examination of patients who complained of headache at the time of the examination, we have recently practiced the simple procedure of local infiltration of the scalp with procaine hydrochloride (1 or 2 per cent) or isotonic solution of sodium chloride. This procedure usually brought relief within a few minutes after injection of either solution when carried out on patients with psychogenic headaches but patients with headaches due to migraine or cerebral tumor were not relieved. It was interesting also that in the patients who did experience relief an injection on one side of the scalp generally relieved the headache in that half of the head, and a subsequent injection on the other side relieved the rest of the ache. These results can be explained only by the assumption that the relief experienced was purely on the basis of suggestion, and it is interesting to note that the patients with psychogenic headaches were uniformly much more suggestible than those of the other two groups tested. A lasting therapeutic effect was not obtained by the procedure in any patient, and its only value, in our opinion, would be as a roughly reliable diagnostic guide in patients who present themselves to the physician for the first time with an acute headache.

Like the investigation of the patient with chronic headache, the treatment should be twofold: pharmacotherapy and psychotherapy. As the former is the more familiar, we may conveniently begin with it.

In the treatment of migraine, derivatives of ergotamine are generally accepted as the medication of choice. As is well known, these drugs are useful only in relieving an acute attack. The commonest cause for failure to achieve satisfactory relief is the use of too small a dose of medication, and for this reason it is important to administer the full therapeutic dose of whatever preparation is used. In our experience we have found that the relief afforded by ergotamine derivatives is often considerably enhanced by the addition of a dose of one of the short acting barbiturates at the beginning of the attack.

For the relief of a post-traumatic or psychogenic headache the most satisfactory medication is one of the usual analgesics (salicylates or acetophenetidin), to which may be added caffeine and one of the short or medium acting barbiturates. The use of codeine or other narcotics is contraindicated for obvious reasons.

Endocrine therapy has been recommended by many authors for various types of headache. Eight of our patients with menstrual or premenstrual headaches were given testosterone propionate (30 to 100 mg. in divided doses both orally and intramuscularly) with considerable improvement in 2, moderate improvement in 3 and no improvement in 3.

Twenty-four patients were treated with beta dimethylaminoethyl benzhydryl ether hydrochloride (Benadryl) in oral doses up to 200 mg. daily. Five of these patients had migraine, and 19 had psychogenic headaches. Each of the patients with migraine and psychogenic headaches reported doubtful relief, but none of the others noted any improvement at all.

Octin mucate (2-methyl-6-methylaminoheptene-[2]) has recently been recommended for patients with migraine.[2] We have given it to five patients in oral doses of 4 to 6 grains daily. Four patients did not experience relief. The other was improved, but as the improvement coincided with her husband's return from service, it is difficult to know whether to attribute the therapeutic success to the medication or not. A new ergotamine derivative, D.H.E.-45 (dihydroergotamine), has recently been reported to be superior to ergotamine itself in the treatment of migraine.[3] In our experience the results with D.H.E.-45 seem about equal to those with ergotamine. We have had no success in treating migraine with hapamine (a chemical combination of histamine and despeciated horse serum globulin), nicotinic acid, nicotinamide, thiamine chloride, estrogenic substances or caffeine.

---

[2] Palmer, H. D.: Migraine Headache, Clinics 4: 531 (Aug.) 1945.

It has been our experience that a combination of psychotherapy and drug therapy is much more effective than the latter alone in reducing the frequency, duration and severity of any of the three types of headache which we are discussing. Indeed in the majority of these patients medication is chiefly of value in relieving the discomfort of the acute attack, and it is only by reducing the amount of mental stress to which the patient is subjected that the headaches can be reduced in frequency and severity and often rendered easier to control by suitable medication when they do occur.

To achieve such a result is not equally easy in every case, nor must the means employed be uniformly the same. The psychologic problems vary greatly from patient to patient. In some they may be largely the result of an unfavorable environmental situation which must be changed for improvement to result. In others the difficulty is primarily in the inner life of the patient, with the result that he cannot adjust adequately even to the usual demands of his daily life. Advice as to mental hygiene, reassurance and the opportunity to ventilate his anxieties and conflicts are psychotherapeutic aids which are within the province of the practitioner and which in favorable cases will result in good therapeutic results. In other cases in which the patient's mental difficulties are more severe or more deeply repressed and hence less accessible to therapeutic influence, it seems best to refer the patient to a specialist. We would emphasize, however, that there is at least a large group of these patients who will respond satisfactorily to the type of psychotherapy described, which is well within the province of the general practitioner.

Two cases will serve to illustrate the symptomatic improvement that may follow the lessening of environmental stress in patients with headaches.

REPORT OF CASES

Case 2.—B. P., a 29 year old, married housewife, had suffered with migraine for nineteen years. During the eighteen months before her first visit, the attacks had been particularly frequent and incapacitating. They were preceded by scintillating scotomas and some blurring of vision in the left visual field, were accompanied by nausea and vomiting and were limited to the right side of the head. On examination she was found to have a homonymous defect of the left visual field, and for this reason she was hospitalized. Complete studies, including electroencephalogram and pneumoencephalogram, failed to show any evidence of an expanding intracranial lesion, and the final diagnosis was migraine, possibly with some vascular anomaly of the cerebral cortex. She had two headaches during the month after her discharge from the hospital and none during the two following months. It was learned that her husband had been drafted eighteen months before her first visit, at the time when her headaches began to get worse. During his absence she managed his small business, which was a constant source of strain and aggravation to her. She could recall many occasions when after a particularly aggravating episode in the store a headache had developed so severe that she had had to go home and go to bed. At the time of her entry into the hospital her husband was released from service and resumed operation of the business himself, so that when she left the hospital she was not only reunited with her husband but relieved of the necessity of working away from home.

Case 3.—H. G., a 62 year old widow, came to the hospital complaining of generalized headaches of over a year's duration, which had become so frequent and severe that she had been unable to work even part time during the four months before her visit. In the course of the initial interview, it became clear that the patient was extremely anxious about her only son, who was on hazardous duty in the Southwest Pacific. She was given an opportunity to air her anxieties at that and during the next visits. Physical and laboratory examinations did not reveal any abnormality, and she was placed on salicylates. To this medication she attributed the complete relief of her headaches, though in fact it was the advent of V-J day which was responsible for the striking therapeutic result. She has had no recurrence of her headaches, despite discontinuance of all medication and has been able to return to her old work. In her case the exacerbation of her symptoms during the last few months of the war were clearly related to the increasing anxiety for her son's safety as the hour for cessation of hostilities drew near.

The following report is a good example of a patient whose headaches were improved by simple psychotherapy, consisting chiefly of reassurance and an opportunity for him to discuss and air his anxieties about some relatively superficial problems.

Case 4.—G. Z., a 32 year old attorney, had been suffering from attacks of migraine since his graduation from law school, four years previous to examination. Nothing noteworthy was revealed on physical or neurologic examination. Ergotamine tartrate was helpful in controlling or alleviating the attacks, but even with its help the patient was not always successful in avoiding severe discomfort. After some study it was ascertained that the migraine headaches occurred most often the evening before the patient was to appear in court or on a Sunday when he did not do any work at all. It also became apparent in the course of successive visits that the patient exhibited considerable evidence of psychologic tension. After a period of psychotherapy and adjustment, the patient became able to attend court without precipitating an attack and to enjoy his holidays. The frequency of his attacks was markedly reduced, they became of shorter duration and were now invariably relieved by the use of ergotamine tartrate. This improvement lasted for fifteen weeks, following which his headaches again became more frequent. After some discussion, it was learned that his wife was nearly at term and that he had considerable anxiety about her prospective delivery. In the course of further interviews he was given opportunity to discuss his anxieties more fully and was reassured. Since that time, four months ago, he has been free from headaches.

A final example may serve to illustrate the difficulties which may be encountered in certain cases in trying to influence the unfavorable psychic constellations which are present.

Case 5.—N. T., a 26 year old business man, sought relief for recurrent, severe, bitemporal headaches since a minor head injury at the age of 11. He had been to many hospitals and physicians, and though he had always been told that there was nothing physically wrong with him, he had never been able to get relief from his headaches, which were often so severe that he had to leave his work and go home. In the course of a series of interviews, it became apparent that the patient had an intensely ambivalent attitude toward his father, with whom he was in close daily contact. Discussion of this relationship in a series of weekly interviews was accompanied by considerable diminution in the frequency and severity of the headaches, which after a lapse of four weeks in the treatment returned as severely as before. Because of the nature of the patient's conflict, intensive psychotherapy was advised, but it proved impossible to arrange this.

[3] Horton, B. T.; Peters, G. A., and Blumenthal, L. S.: A New Product in the Treatment of Migraine: A Preliminary Report, Proc. Staff Meet., Mayo Clin. 20:241 (July 11) 1945.

ACC-MO-50

SUMMARY

1. Patients with migraine, post-traumatic and psychogenic headaches constitute the majority of all patients with chronic headache and represent a challenging therapeutic problem to the practitioner.

2. The mechanism of pain production is probably vascular in all three groups, and in each the headaches are readily precipitated and made worse by emotional stress and inner conflicts.

3. For this reason psychiatric study of the patient with chronic headache is as important as physical and laboratory examinations.

4. A new, simple, diagnostic procedure which is described is of service when the patient is seen during an acute attack of headache, and warning is issued against diagnosing headache as psychogenic on the basis of the distribution or character of the pain of which the patient complains.

5. For best results in treatment in most cases, psychotherapy is as important as drug therapy. Simple psychotherapy, such as lies within the province of the general practitioner, is often effective therapeutically. Such therapy is discussed briefly, as is drug therapy, and illustrative cases are cited.

ABSTRACT OF DISCUSSION

DR. CHARLES D. ARING, San Francisco: Headache probably is the symptom to which the flesh is most commonly heir. The populace receives relatively meager help in this disorder from the medical profession. We possibly are influenced more than we like to admit by the advertisements and have fallen in with suggestions that headache is amenable to whatever concoction pharmaceutical houses are otherwise unable to dispose of. Dr. Sullivan of New York some years ago exhibited a chart at one of the national meetings diagraming the good results reported by various authors for the multitude of drugs and manipulations used in treating headache. As I recall, it was demonstrated that almost anything may relieve attacks of headache in some 70 to 90 per cent of instances. Isn't it remarkable with all this relief floating about that the cures of headache are extraordinarily rare? Yet cure is within the accomplishment of many practitioners if they will follow the tenets outlined by Drs. Friedman, Brenner and Merritt. The only cure for headaches of emotional origin, which comprises about all of them, is psychotherapy, which is time and energy consuming and demands the best interests and intelligence of the practitioner of medicine. Resigned listening, awaiting the opportunity to interrupt will not do; nor will psychotherapy be successful in a single interview. It is only after several interviews with the understanding and informed physician that the patient may obtain some awareness of the mechanism of his headaches. When this occurs the road to recovery is no longer a thorny one. Diagnosis is always going to be knavish, and all of us are going to miss the occasional case of brain tumor or chronic malaria, particularly if we do not retain them in mind as possibilities, yet this will hardly justify the casualness with which we have handled this common problem in pain. While it is clear that vasodilatation, particularly of the external carotid system, is usually present during the pain of the migraine episode, it must never be lost sight of that the dangerous part of the syndrome is the preceding cerebral vasospasm, which may manifest itself by neurologic signs, the most common being scintillating scotoma and hemianopsia and numbness or tingling of one or both extremities of the same side. Less frequently one observes weakness and dysphasia, and sometimes weakness proceeds to a rather complete and not readily reversible hemiplegia. It is probably not widely known that people who have suffered from migraine most frequently die with cerebral softening. There is hardly any excuse for offering the public new substances which do not cure headache. It is reasonably safe to say that those drugs which we already have, including acetylsalicylic acid, properly and honestly exhibited will equal whatever preparations are brought forward.

DR. J. M. NIELSEN, Los Angeles: Dr. Friedman has been working with a certain group of patients. The outpatient department is usually the place to which ambulatory patients come, and usually the younger patients. When Dr. Friedman was working with us in Los Angeles in the wards of the General Hospital, where the patients are nearly all old, he had an entirely different source of headache, the so-called arteriosclerotic headache. Even in private practice among the aged we have that as a constant problem, and I do not think that we are dealing chiefly with migraine or chiefly with psychogenic cases. I have difficulty differentiating between migrainous and psychogenic headaches. After all, they work through exactly the same mechanism. I have a woman now who is highly intelligent, suffering with migraine. She had been diagnosed in Pittsburgh and had been successfully treated, but she said herself "My trouble is now, Doctor, that I wake up in the morning and say to myself 'I wonder if I am going to have another headache' and in about two minutes it begins. And if I never stop to think whether I am going to have one, then it doesn't come nearly as frequently." It seems to me that there are innumerable causes even of migraine. It is extremely difficult for me to delineate the syndrome. There is the case of the happily married woman who had no difficulty until a certain religious sect opened up a tent for an evangelistic revival in her city. She attended and became a convert. She tried to get her husband to go. They had considerable conflict, of course, but she became a convert and left her husband, joined the new sect and became an ardent worker. In this sect a vegetarian diet was compulsory, and she immediately went on a vegetarian diet. In three months she began to have what was considered a migraine headache. In a month she had another, in two weeks another, and by the time I saw her she had one every other day. I thought perhaps it was her acid-base balance that had been disturbed, but I could not put her back on meat; after all, her soul was more important. So I put her on diluted hydrochloric acid with each meal. She reported repeatedly for months back to the clinic and never had another headache. I have difficulty with the diagnosis. I think every case is a challenge, and I simply don't have any rule.

DR. SAMUEL B. HADDEN, Philadelphia: About seven years ago, under the title of "Neuralgic Headache and Facial Pain" (*Arch. Neurol. & Psychiat.* **43**:405 [Feb.] 1940) I reported headache similar to that which the authors have described. At that time I attributed most of these headaches to involvement of the occipital nerves in a fibrositis of the posterior neck and scalp muscles, but recognized that many of them were part of the symptom complex of a psychoneurosis. I reported that procaine was effective in giving prolonged as well as temporary relief. There is general agreement with the statement of the authors that the headache of migraine is on a vascular basis, but I do not believe that many of the headaches seen in the psychoneuroses are on such a basis. I feel that the headache of the psychoneurotic patient is more probably the result of the fatigue incident to tension and overacting scalp muscles. Many patients who suffer with this type of headache have discovered that periods of relaxation and gentle massage of the scalp muscles effect relief. In dealing with a large group of psychoneurotic servicemen, in whom headache was a frequent symptom, the puckering of the brow into a frown was so common that the group began to refer to those in this category as the "prune faced section." With instruction in how to relax, these patients were prone to experience prompt relief even early in the course of a program of psychotherapy. I would suggest that local heat, massage and instruction in the relaxing of the scalp and posterior neck muscles be considered as effective adjuncts to the symptomatic relief of these patients during their psychotherapy.

DR. WALTER FREEMAN, Washington, D. C.: I might as well take issue right from the start with Dr. Friedman and his colleagues and say that one of the best ways of relieving a migrainous headache is to inject a little procaine around the artery, whether it is temporal, occipital or frontal. Further-

Dr. Robert Heilig Library

more, in quite a number of cases my colleagues and I have secured permanent relief of migrainous headache by resection of a short piece of one of these arteries. It would be interesting in the psychogenic headaches, on the other hand, to have a test which would give some information concerning both the severity of the headache, the production of the headache and also the reaction of the patient to the headache. One of the most satisfactory tests to determine what sort of patient one has is to apply the Libman test for individual sensitivity to pain. That consists in pressing over the mastoid processes, which are insensitive, in order to accustom the patient to the idea of pressure, then bring the thumbs forward over the styloid processes, where pain should be felt by the normal person. There is a great deal of variation in individual sensitivity to pain. Dr. Libman pointed out that prize fighters can almost be lifted up by their styloid processes without producing pain. Others complain of pain the moment one presses on the mastoids a little bit. The second test I have found of value in these psychogenic headaches is the hyperventilation test. Often these headaches, so called, will be accompanied with symptoms such as dizziness, light headedness, coldness of the fingers and maybe palpitation, vertigo and dyspnea. Have you ever had a patient stand up and hyperventilate for one minute? You often see them contract their brows into the "prune face," and they will experience severe headache. If you stop the hyperventilation and have them attempt to hold the breath for a period of two minutes, the headache often disappears. Dr. Nielsen mentioned the value of hydrochloric acid in some of these cases. I think there must be some upset in the acid equilibrium on the emotion and hyperventilation basis that many of these patients show. The addition of hydrochloric acid or ammonium chloride to the intake of these patients is only a palliative measure; nevertheless, when one is dealing with a psychogenic headache for which the psychogenesis may not be appreciated by the patient or the situation may be incorrectible, sometimes a palliative remedy is satisfactory, and in this connection we have to remember that acetylsalicylic acid is a rather strong acid.

Dr. Matthew T. Moore, Philadelphia: From what has been offered by the authors, I fear there is too great a temptation, at times, to attribute a psychogenic etiology to many patients suffering from migraine in whom possible organic factors have not been fully investigated. At present I have a series of patients with a history of true and severe migraine who had been subjected to psychotherapy and prolonged psychoanalysis and who have been given various medicaments without avail. In these cases with hemicrania of long duration I have utilized the procedure, advocated by Watts and Freeman, of resecting a small segment of the temporal and supraorbital arteries, with very satisfactory results. Have the authors used this method, and if so what have the results been?

Dr. Foster Kennedy, New York: Being neuropsychiatrists, I suppose it is beneath our notice to realize that the primary ego is the gastrointestinal tract! In all this discussion I have not heard the word "constipation." One would hear it in internal medicine gatherings. Constipation is really the most common cause of prolonged headache: a simple idea, but one surely not to be forgotten. I have cured many headaches by reducing water intake. The idea of "forcing fluids" has been a ritual for fifty years on this continent. Every nurse says it in her sleep. The result is that patients think that by taking eight, ten or twelve glasses of water in a day, being nearer they think to cleanliness, they may be nearer too to godliness. By reducing fluids to 1 or 1½ quarts a day, one can frequently stop recurrent severe headache due to water balance chronically disturbed. Nor have I heard any one say anything of the allergic characteristics of migraine which must be considered in any general survey of this subject.

Dr. Arnold P. Friedman, New York: We thank the discussers for their interesting remarks. We agree with Dr. Aring and Dr. Nielsen regarding the importance of psychogenic factors in the production of migraine headaches. In answer to Dr. Hadden's questions, we also use a certain amount of physical therapy in the form of warm baths and comfortable support for the head during a headache. Our experiments with procaine injection seem to indicate that suggestion is the most important factor in producing relief from headache by such injection. In our opinion the essential thing to treat in these patients is the underlying anxiety and emotional tension. Dr. Freeman's suggestions are interesting. Not being neurosurgeons, we have not resected any arteries ourselves. However, we have had opportunity to observe several cases in which this has been done, and in these the therapeutic results were not always as gratifying as in the ones Dr. Freeman has just reported. Dr. Moore's remarks about the importance of organic factors are well taken. Each patient coming to us was given a careful physical and neurologic examination, routine laboratory studies and in most cases x-rays of the skull and an electroencephalogram. Dr. Kennedy of course has had tremendous experience in treating these cases. So far we have not been impressed by the importance of allergy, constipation or water retention in most cases of chronic headache. The patients whom we have tried on salt poor diets with low fluid intake have had no relief from their headaches as a result of this regimen. The majority of persons whom we have tested show a positive test for histamine regardless of their susceptibility to chronic headaches. As is well known, histamine sensitivity is not a true allergic phenomenon

INSULIN IN THE TREATMENT OF DIABETES MELLITUS

LESTER J. PALMER, M.D.
Seattle

In this year, 1946, the twenty-fifth anniversary of the great discovery by Banting and Best, it is fitting to summarize the majority opinion and the present policies of the large diabetic clinics of the nation in regard to the use of insulin in the treatment of diabetes mellitus. In this paper I shall present a summary of the information on this subject which I have obtained through personal and written contact with the many diabetic clinics of America, including the one with which I am associated.

It should give this audience great confidence in the basic soundness of the present conception of the correct use of available insulins to know that the information from these many sources indicates a remarkable uniformity of policy.

THE HISTORY OF INSULIN

It would be negligent to omit from a discourse such as this a few brief remarks on the history of insulin. Banting and Best completed the animal experiments and established proof that insulin lowered the blood sugar concentration and diminished the glycosuria in diabetic dogs, in the autumn of 1921. Insulin was first administered to a human diabetic, a boy aged 15, at the University of Toronto in January 1922. Collip furnished the plan and Eli Lilly and Company, in collaboration with others, contributed extensively to the production of insulin on a commercial basis. This original insulin became available to the medical profession in January 1923 and to the public six months later.

From the Mason Clinic, Virginia Mason Hospital.

Read in the General Scientific Meetings at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 2, 1946.

Personal communications to the author were received from Elliott P. Joslin, Howard F. Root, and Priscilla White, of Boston; Russell M. Wilder, Randall G. Sprague, Samuel F. Haines, Edwin J. Kepler and Edward H. Rynearson, Rochester, Minn.; Franklin B. Peck, Indianapolis; R. T. Woodyatt, Chicago; W. D. Sansum, Santa Barbara, Calif.; Cyril M. MacBryde, Los Angeles; James E. Paullin, Atlanta, Ga.; J. W. Conn, Ann Arbor, Mich.; H. Clare Shepardson, San Francisco; Cecil Striker, Cincinnati; Joseph H. Barach, Pittsburgh; Edward S. Dillon, Philadelphia; Frederick W. Williams, New York; Henry J. John, Cleveland; Howard F. West, Los Angeles, and Blair Holcomb, Portland, Ore.

An arbitrary standard unit was defined early; it was soon increased by about 50 per cent. The method of standardizing fresh productions of insulin and the definition of the unit have been changed several times since 1923. The last change was made in 1942, when the last Pharmacopeia of the United States (U. S. P. XII) published the currently employed standard. Potency is now expressed in U. S. P. insulin units, which are equivalent in potency to the unit declared on the label of the container of this standard which is furnished for comparative purposes by the U. S. P. Committee.

Amorphous, or regular, insulin of approximately current unit strength remained the only available commercial insulin until 1937. The need for long-acting insulin was evident for many years before it became available. The cases of mild diabetes characterized by spontaneous normal fasting blood sugar had never been a difficult problem. The abnormal postprandial rise of blood sugar and glycosuria in this group, if not corrected by a minimal yet adequate diet, was easily controlled by one or two injections of quick-acting original insulin. But the cases of severe diabetes with a distinct tendency to a nocturnal rise of blood sugar constituted a problem calling for a long-acting insulin, of which a single injection each twenty-four hours would be effective in controlling this feature.

Thus, in 1935, the search for such an insulin was consummated by the development by Hagedorn of protamine insulin. This was later perfected as protamine zinc insulin by the Toronto group and, after clinical trial, became available commercially in February 1937. Eighteen months later, in August 1938, solution of zinc insulin crystals, commonly known as crystalline insulin, became available commercially.

Most recently globin insulin with zinc has been marketed by two manufacturers. It acts more quickly than protamine zinc insulin and less rapidly than regular or crystalline insulin; its action persists longer than that of regular or crystalline insulin but definitely for a shorter period than that of protamine zinc insulin. It produces its peak effect in about eight hours and expends about 80 per cent of its total effect in the first twelve hours.

For the most part, it was developed at Columbia University and, although highly acclaimed by certain clinics, it is considered an unnecessary insulin by most clinics. It has few, if any, attributes not possessed by the other insulins, when they are used either singly or in combination. It lacks the ability to produce therapeutic results comparable to those obtained by combinations of the other insulins, and this weakness is particularly manifest in patients requiring over 30 to 40 units per day.

AVAILABLE INSULINS

Regardless of the kinds of insulin now available or which may become available, and of whatever method of applying them to the treatment of diabetes in man is to be accepted as most logical and rational, the pharmacologic action and the method of application must accord with current knowledge of the disordered physiology characteristic of the disease and must be consistent with the experience gained from the treatment of diabetes with insulin during the past twenty-five years.

Diabetes may be produced experimentally in animals by three methods: subtotal pancreatectomy, the administration of large quantities of crude pituitary extract, and the administration of alloxan. Regardless of the method employed, the result is a loss of ability to produce sufficient insulin to meet the demand of normal metabolism. Again, whether there is a full acceptance of the overproduction or underutilization theory of diabetes, all concerned are willing to accept without question the fact that extraneous insulin administered parenterally controls the clinical symptoms of the disease, and causes glycosuria to disappear and glycemia to approach normal.

There are available now for treatment against diabetes two principal types of insulin: (1) quick-acting–short-acting insulin, namely—either amorphous (or regular) insulin or solution of zinc insulin crystals, known as crystalline zinc insulin; and (2) slow-acting–long-acting insulin, namely—protamine zinc insulin.

HOW MANY DIABETICS REQUIRE INSULIN?

Most estimates state that the number of persons known to have diabetes in the United States today approaches 1 million. At least one half of this number at large are using insulin, and among those patients seen in diabetic centers or clinics the percentage of users is as high as 85 per cent. It seems likely that many of the 50 per cent who are not using insulin today should be using it with consequential benefit. Estimates indicate that perhaps somewhat less than 50 per cent of the total known cases of diabetes today may be controlled, for the time being at least, without insulin on a diet adequate from all nutritional points of view but necessarily at a minimum calorie level. The remainder of the group require insulin for control. Of these about one-half may be controlled on protamine zinc insulin alone.

The average total daily dose of insulin is about 40 units. Many patients require less, and seldom is there need for as much as 100 units a day. The Mayo Clinic reports indicate that total pancreatectomy in man creates a demand for about 40 units of extraneous insulin per day.

ONE OR BOTH KINDS OF INSULIN?

Although protamine zinc insulin is a remarkable insulin and fills many long felt needs, it has definite shortcomings. Approximately 60 per cent of the effect of any dose of protamine zinc insulin is released in the first twelve to fourteen hours after injection. Therefore, it is always injected before the first meal of the day. This is logical, since the greater part of the effect of the dose is thus exerted during the hours when food is taken. The total practical dose, however, must be based on the blood sugar levels during the second twelve to fourteen hours after injection. This dose must not exceed the amount which produces a blood sugar level that approaches normal but does not reach reactionary levels during the night and before breakfast. A sugar-free, or nearly sugar-free urine during these hours is a desired objective. Because of this pharmacologic characteristic of protamine zinc insulin, in only about one half of those diabetic persons who require extraneous supplementary insulin can the disease be satisfactorily controlled on this insulin alone. When the total insulin dosage exceeds 30 or at most 40 units it will be found that the amount of insulin which satisfactorily controls the blood sugar level at night fails to meet the demands for extraneous insulin during the day. As a result, blood sugar levels during the day exceed those considered desirable for good control, and excessive glycosuria results. To meet this situation, it is necessary to add to the regimen an appropriate amount of quick-acting insulin administered at the same time as protamine zinc insulin. Most clinics prefer crystalline insulin for this purpose.

ROUTINE MANAGEMENT

Many tables are available to enable the physician to prescribe a diet based on the ideal weight, which takes into consideration the basal calorie requirement plus calories for activity. The most commonly employed diet supplies 40 per cent (or somewhat less) of the calories as carbohydrate, 15 per cent as protein and 45 per cent (or somewhat more) as fat. This distribution will insure adequate vitamins, minerals, bulk and fluid. Begin treatment with the basal requirement or less and gradually increase the diet to the maintenance level. If one must err in prescribing the diet, either on the side of undernutrition or overnutrition, slight undernutrition is safer. This principle, enunciated by Allen in 1915, still holds.

The decision on whether or not to employ insulin at the beginning of treatment will be based on the severity and duration of symptoms, the degree of hyperglycemia and glycosuria and, finally, on the judgment and experience of the physician. Some will try response to diet alone at first. Early use of insulin will, however, bring about prompter control, permit earlier use of adequate diets and insure practical instruction in the use of insulin, which should be a part of the knowledge of every diabetic person. Of course, acidosis and complications always require insulin, and rarely should one attempt to treat diabetic children without insulin.

In the routine care of diabetes in which insulin is used, protamine zinc insulin is the primary or fundamental insulin, always given only once a day and before breakfast. The maximum dose which may be safely used is indicated by the fasting blood sugar level and/or the presence or absence of sugar in that specimen of urine which has not been in the bladder more than thirty to forty minutes before breakfast. It is safe to start with 10 units and increase 5 or 10 units every twenty-four to forty-eight hours until the fasting urine is sugar-free. Experience may indicate a higher starting dosage. It is universally observed in diabetic clinics that when the total insulin requirement exceeds 30 or at the most 40 units, it becomes necessary to supplement the effect of protamine zinc insulin with quick-acting insulin to counteract daytime hyperglycemia or glycosuria. Further increase of the protamine zinc insulin alone usually results in night-time hypoglycemia even though the daytime glycosuria is ultimately controlled. Routinely this supplemental quick-acting insulin is given as a separate injection at the same hour as the protamine zinc form. The amount required is oftenest about 1 unit of crystalline insulin to 2 units of protamine zinc insulin. The ratio may be less or occasionally greater than 1:2.

It may be necessary during the early period of use of supplementary insulin to use additional doses before lunch or supper, but in a short period of time these additional doses may be stopped. Experience may enable the physician to select those patients in whom the use of crystalline insulin with protamine zinc insulin at the start of treatment will shorten the time required to bring the diabetes under control.

It is ideal and helpful to have access to laboratories for blood chemistry, even in the routine care of diabetes, but it is not essential. There should be a greater number of accessible laboratories, but exceedingly efficient care can be based on urinalyses alone, employing single specimens, twenty-four hour collections and fractional collections.

Rather promptly after treatment is instituted there is frequently observed a sharp drop in the insulin requirement, especially if the diagnosis has been made early. The physician should not be influenced by this observation to suspend the use of insulin too quickly, even when this seems possible; continued rest of the island of Langerhans cells through the use of insulin early in the course of treatment may prevent some of the ultimate atrophy that leads to a future increase in the degree of insulin deficiency. Usually during the first year of treatment the insulin requirement will rise after the initial drop and then stabilize for a considerable period of time.

INSULIN DURING COMPLICATIONS

During complications, specifically infection, injuries, surgical procedures, acidosis and pregnancy, additional insulin is almost always required. This additional insulin should be the quick-acting type and should be given as separate injections every six hours. It is emphasized that this is additional insulin; that is, it is in addition to what the patient is currently taking, whether that be no insulin, protamine zinc insulin alone, or protamine zinc plus quick-acting insulin. This additional insulin is best given in an additional number of injections.

Infections and Injuries.—In the presence of infection, mild or severe, the basic insulin arrangement is not changed, but additional quick-acting insulin is given every six hours as indicated on the basis of the urinalyses. Injuries usually increase the insulin requirement, and changes in insulin administration are made in the same manner.

Surgical Procedures.—Although some authorities prefer to continue, during the operative and postoperative period, the amount of protamine zinc insulin usually taken by the patient, it is my opinion that the uncertainty of gastric feeding makes it safer to suspend the administration of protamine zinc insulin during this period. I prefer to use only quick-acting insulin every four to six hours, as indicated by the results of a urinalysis or by the blood sugar determination. A solution of dextrose in the amount of 125 to 150 Gm. per twenty-four hours is administered.

The surgeon dictates how long intravenous administration is to be continued and when oral feeding is to begin. Also, he decides when the type of food is to be changed from liquid to soft or from these foods to full diet. The internist should order all fluids during the postoperative period, the quantity to be decided by the surgeon and internist.

It is my practice to give 25 Gm. of quick-carbohydrate together with 25 per cent of the total number of units of insulin usually taken, as crystalline insulin, three hours before surgery and to divide the balance of the usual dose of insulin into equal amounts to be administered before each 1,000 cc. of 5 per cent dextrose solution which is given during the first twenty-four hours. During subsequent days the dosage may be based on four to six hour urinalyses as first mentioned, or the total amount to be given may be divided arbitrarily into equal amounts administered before each intravenous glucose or oral feeding. To a considerable degree, during that period when glucose is being given intravenously the insulin requirement will be controlled by the judgment of the physician based on his experience with surgical diabetic patients and by his knowledge of the individual patient. This is so because urinalyses and even blood sugar determinations are rather unreliable under such conditions.

Near the end of the postoperative period and before discharge, control of the diabetes is again adjusted with protamine zinc insulin alone, or with protamine zinc plus crystalline insulin if necessary.

Pregnancy.—Insulin has made conception common among diabetic women. Insulin has increased considerably the percentage of successful terminations of pregnancy. There are many who still believe that good diabetic control throughout pregnancy is the most important factor in success. An increasing number of authorities, however, feel that substitutional hormone therapy is necessary to attain 90 per cent fetal survival as reported by White.[1] Increasing clinical evidence supports this opinion.

The insulin requirement during pregnancy may rise, fall or remain fairly constant. The usual insulin regimen followed by the patient will apply when diabetes exists before the onset of pregnancy. When diabetes develops during pregnancy the usual methods of instituting the use of insulin, as previously outlined under routine management, are to be employed.

To even a greater degree than usual the use of insulin during pregnancy must be distinctly individualized. The urine test during pregnancy is definitely unreliable as a guide to dosage because of the lowering of the renal threshold for dextrose. Therefore, to intelligently direct insulin dosage during pregnancy blood sugar determinations as often as bi-weekly are almost essential. Sufficient insulin to produce complete aglycosuria almost invariably results in reactions.

During pregnancy, protamine zinc insulin remains the basic form, and if control is not accomplished with this insulin alone, supplementary crystalline insulin is added to the regimen. In the absence of complications it is seldom necessary to give more than one injection of each type of insulin a day.

At delivery, the insulin arrangement will depend on the method of delivery. Spontaneous labor represents active exercise, and frequently not only less insulin but additional carbohydrate is necessary. If delivery is to be accomplished by cesarean section, insulin arrangement is comparable to that employed during any surgical procedure. Barnes and I[2] prefer to suspend the use of protamine zinc insulin and use only crystalline insulin every four to six hours as indicated.

Immediately after delivery there is a sharp reduction in the insulin requirement, regardless of intravenous or oral feeding. Frequently little or no insulin is required for twenty-four to as long as seventy-two hours. This is true even when the daily dose of insulin before delivery has been as much as from 50 to 60 units. Insulin must be administered cautiously during this period.

Coma.—Insulin is the specific remedy in diabetic coma. Fluids and salt are necessary but not specific. The disordered metabolism of fat is in control of the organism during severe acidosis and coma, and recovery depends on a shift to the metabolism of carbohydrate. Only insulin will accomplish this.

A word of caution before the initiation of treatment is necessary: Be certain of the diagnosis of diabetic coma; additional insulin administered to a patient in severe insulin shock may be a lethal act. It is safest to have laboratory support of clinical evidence. Glycosuria with ketonuria in an unconscious patient does not always indicate diabetic coma. Before large doses of insulin are given, blood sugar and carbon dioxide combining power levels in the blood should, if at all possible, be determined. Coma is truly an emergency, requiring hospitalization whenever available.

As soon as diagnosis is certain, the first insulin is to be given at once. The insulin given in the first hour of observation is at least several times as effective as that given three or four hours later.

The total insulin required to correct diabetic coma may vary from less than 100 units to as much as 2,000 or more units. The amount of both the initial dosage and the total dosage is greater in proportion to: the duration of the diabetes; the amount of insulin used regularly; the duration of the acidosis, and the degree of seriousness of the complication. Although some authorities employ an initial dose of protamine zinc insulin in coma, I discourage this practice. It is too slow-acting for any emergency, and quick-acting insulin must be employed, regardless; once a large dose of protamine zinc insulin is given, the physician has lost control of insulin dosage for twenty-four hours, and, lastly, it may lull one into a false sense of security during a critical perod when prompt and sufficient insulin effect is essential.

This initial dose of quick-acting insulin varies from 20 to 40 units and from this amount up to 100 units. The average patient will receive 40 units subcutaneously. Knowledge of the patient and judgment based on experience may justify larger doses, as much as 100 units, especially when the degree of coma is pronounced, when shock is present and when blood sugar levels are high and carbon dioxide levels in the blood are low. Children require smaller fractional and total dosage than adults. When conditions are urgent, one-half the initial dose may be given intravenously.

Insulin must then be repeated every thirty to sixty minutes subcutaneously in appropriate dosage, guided by clinical and laboratory evidence of response, until the patient has recovered.

In the opinion of most authorities, and of myself as well, it is unnecessary, harmful and illogical to give dextrose to a patient in coma until there is evidence that sugar already in the tissues is being oxidized. This will be indicated by clinical improvement, a falling blood sugar level, a decreasing glycosuria and a rising level of carbon dioxide combining power. Most authorities prohibit the use of dextrose by vein or mouth until the urine is practically sugar-free.

Some clinics employ alkaline intravenous solutions in the treatment of coma; most clinics do not. Those who do use them, reserve them for patients in diabetic coma of decided severity and for times when the carbon dioxide combining power is low and is slow to rise toward normal. Although a few authorities consider alkaline intravenous solutions harmful, most authorities believe that they are harmless but nearly always unnecessary. Again, it should be repeated that insulin is the specific.

[1] White, P.; Titus, R. S.; Joslin, E. P., and Hunt, H.: Prediction and Prevention of Late Pregnancy Accidents in Diabetes, Am. J. M. Sc. **198**: 482-492 (Oct.) 1939.

[2] Palmer, L. J., and Barnes, R. H.: Pregnancy in the Diabetic, West. J. Surg. **53**: 195-202 (June) 1945.

Two important points should be emphasized. Coma is a continuous emergency. Remain with the patient continuously to direct the dose of insulin and other therapeutic measures until clinical recovery occurs, and watch the patient closely for twenty-four hours longer. A relapse into coma may occur if treatment is discontinued too soon. Because of the overlapping effect of previous dosage, a sharp reduction in the amount of insulin to be administered is necessary for as long as twenty-four hours after recovery from the coma is complete.

Edema and the Insulin Requirement.—The insulin requirement is altered in the presence of edema. In the presence particularly of congestive heart failure blood sugar levels usually fall, and insulin requirement drops. The physician, although he takes cognizance of this fact, should not be deceived but should watch for the return of higher insulin requirement when compensation is restored.

THE INSULIN REACTION

The seriousness of insulin reactions is probably overrated. If a half million diabetic persons take insulin each day, the percentage of accidents and possible deaths is extremely low. Patients should be taught the significance of regular meals, early recognition of the symptoms or reaction and the importance of prompt treatment. *It is dangerous to allow a patient to remain* in hypoglycemia long, and it is doubly dangerous to administer insulin to an already hypoglycemic patient. In case of reaction, give dextrose early; continue it until the symptoms have been relieved and, if the patient has been unconscious from hypoglycemia for a long time, administer small amounts of carbohydrate continuously until recovery is complete.

THE INSULIN SYRINGE

Brief comment in regard to the insulin syringe is necessary. Insulin should always be measured in a syringe intended only for insulin. There are far too many types of insulin syringes available commercially. The dose of any kind or strength of insulin should be measured only on a scale intended for that particular strength. That is, 40 unit on a 40 unit scale and 80 unit on an 80 unit scale. Some physicians prefer a universal type of scale on the syringe used for measuring insulin. On such a scale, any strength of insulin may be measured with minimum chance of error. This syringe is a 1 cc. or possibly a 2 cc. syringe graduated into divisions of 0.01 cc. each. It is hoped that the American Diabetes Association will endorse and recommend an official insulin syringe.

MORE RECENT METHOD OF USING INSULIN

During the past two or more years a method of mixing crystalline insulin and protamine zinc insulin in the same syringe or in a bottle prior to administration has been given a trial. The comment regarding mixtures in this paper refers to those mixtures where the two insulins are thoroughly mixed, one with the other, either in the syringe or in a sterile bottle. Peck[3] and Colwell[4] have published the most comprehensive studies. The feasibility of mixtures is based on the fact that standard protamine zinc insulin contains a definite amount of unsaturated protamine. When crystalline or regular insulin is added to protamine zinc insulin this unsaturated protamine combines with the insulin up to the point of saturation. When more than sufficient crystalline to complete saturation is added to the protamine form, uncombined crystalline insulin remains in the mixture in varying amounts, depending on the proportions of the mixture. Nothing less than equal parts is logical. The most commonly employed proportion is the 2:1 mixture (two parts crystalline to one part protamine zinc insulin), although the proportions may be adjusted to the particular needs of the patient. Thus, it may be found that 3:1, 3:2, 4:3 or 5:3 is best suited to a given patient. This variation of the proportions employed in a mixture creates a flexibility which permits a more or less tailor-made pharmacologic adjustment of the insulins to the individual patient, if such fine adjustment is desirable. Of course, the p_H and the zinc content of a mixture differ from those of standard protamine zinc insulin. There is a difference of opinion as to whether or not the insulin effect of a mixture differs from that which would be obtained by administering crystalline and protamine zinc insulin separately in doses computed to give equal effect.

My experience with mixtures used by 156 adult and 72 juvenile patients with diabetes during the past two years leads me to believe that the disease of 25 to 35 per cent of those who require both short-acting and long-acting insulin is better controlled on a mixture than on separate injections; in 25 per cent of the patients on mixtures, the disease is better controlled when the insulin mixture is prepared in a bottle in an amount sufficient for periods of two or three weeks than when there is fresh daily preparation of the mixture in a syringe; 2 parts crystalline to 1 part protamine zinc insulin was the most commonly employed proportion.

Mixtures are definitely on trial and in many large clinics are used only in a small group of especially selected cases or not at all. However, in other large clinics they have been given extensive trial and are held in considerable favor, and in these clinics mixtures are employed at present in the treatment of 50 per cent or more of the patients using insulin. I believe that mixtures will be employed more extensively in the future. As larger groups of statistics become available, a greater appreciation of the advantages of insulin mixtures in the treatment of properly selected patients will be created.

WILL THERE BE NEW INSULINS?

Whereas regular or crystalline insulin, alone or combined with protamine zinc insulin as separate injections or in a mixture, are now in use almost exclusively in diabetic clinics, there is hope and further search for a more satisfactory type of long-acting insulin. It would be an ideal situation if there was one insulin to meet all needs. This goal will probably never be reached because of the variation in 1 diabetic patient as compared to another, and because of the variation in any person with diabetes from time to time. However, any development of a long-acting insulin which would make it possible for more than the present percentage of insulin users to use one insulin once a day would be a distinct step forward. MacBryde[5] has probably had the most extensive experience with such insulins in the form of modifications of the present protamine zinc insulin formula. He has found that a buffered combination which contains less protamine than standard protamine zinc insulin and is known as modified protamine zinc insulin, NP-50, is the most promising. He has based his opinion on his own extensive experience and on the replies to a questionnaire which he, as chairman of the Insulin Committee of the American Diabetes Association, sent to thirteen diabetic clinics. Colwell is of the opinion that the standard protamine zinc insulin could advantageously be replaced with a long-acting insulin represented by a formula which would produce the clinical effects observed in use of the 2:1 mixture.

[4] Colwell, A. R.: Nature and Time Action of Modifications of Protamine Zinc Insulin, Arch. Int. Med. 74: 331-345 (Nov.) 1944.

These are problems of clinical and manufacturing research, and when an insulin which is more satisfactory for a greater proportion of diabetics is perfected, the Toronto Insulin Committe will endorse it.

DEFINITION OF THE CRITERIA OF, AND THE NECESSITY FOR, CONTROL[6]

Much of what has been said in regard to the use of insulin is related to two questions: First, what is meant by "control of diabetes" and what criteria of control are medical practitioners willing to accept; second, is control in the defined sense necessary?

The best reason, it seems to me, for considering as acceptable any criteria of control (approach, at least, to normal blood sugar levels at all times), is that the more nearly the blood chemistry of the diabetic person is restored to normal the more normal the metabolism and the more adequate nutrition will be. Second, is control in the defined sense really necessary? It seems to me that statistics extending over many years of careful observation answer this question as well as it can be answered today. They indicate that if a sufficiently large group of diabetic patients are observed over a sufficiently long period, those whose disease is controlled in accordance with aforementioned criteria suffer less degenerative damage due to their diabetes than do those whose disease is not so managed. It will definitely advance the treatment of diabetes when specific criteria of control are standardized and universally accepted as the yardstick of effective treatment.

Finally, I wish to stress the necessity for the meticulous control of mild and early cases of diabetes, a policy which is not too conscientiously applied either by patient or physician at present. Most practitioners believe that it is only by exacting care of the mild case that there can be prevented or at least retarded the progression from mild to more serious degrees of diabetes. Use insulin too early rather than too late.

[6] Criteria of control: (1) To keep the urine as continuously sugar-free as possible without insulin reactions, and (2) to maintain these blood sugar levels: fasting, not less than 100 nor more than 140 mg. per hundred cubic centimeters, before lunch, not less than 100 nor more than 120 mg per hundred cubic centimeters; two to three hours after lunch, not over 200 mg. per hundred cubic centimeters.

THE ROLE OF DDT IN CONTROLLING INSECT-BORNE DISEASES OF MAN

COLONEL WILLIAM S. STONE
Medical Corps, Army of the United States

In reviewing the diseases of mankind one is impressed by the number of major infections that are transmitted by insects. It is apparent that the most prominent of those diseases are the dysenteries, malaria, the rickettsial diseases in the typhus group, plague, leishmaniasis, trypanosomiasis of Africa and of the Americas, filariasis, pappataci sandfly fever; dengue, encephalitis and encephalomyelitis, possibly poliomyelitis, and a number of other diseases of lesser importance. It is also evident that the causes of these diseases include bacterial, protozoal, nematode, rickettsial and virus agents. The transmitting processes include mechanical transfer as well as complicated intermediate development and propagation of the infectious agent in the insect vector.

This percursory review indicates the importance of controlling or eliminating certain insects in the prevention of human diseases. The United States is fortunate in that it is geographically located where most serious insect-borne diseases have seasonal interference with their transmission and also in that it possesses sufficient resources to allow man to wage a successful and incessant war on harmful and pest insects. While these conditions prevail in the United States, commitments of the armed forces require them to operate in many places throughout the world and far removed from the protected environment which has been developed at home. For these reasons the Medical Department of the Army has had a primary interest in the development of better ways to control insect-borne diseases. Early in 1941 in anticipation of the disease problem that would be encountered, this interest, backed by financial support, material and experienced personnel, led to the formation of an efficient team for the study of insect-borne diseases and the development of practical means for their control. At the Army's request, the Bureau of Entomology, U. S. Department of Agriculture, in conjunction with the Food and Drug Administration and the National Institute of Health, U. S. Public Health Service, began a systematic search for better insecticides and for more effective means to employ those already available. Field tests of promising products were made by the Army, the Navy and Rockefeller Foundation. These studies were coordinated by the National Research Council and later supported by the Committee on Medical Research of the Office of Scientific Research and Development. This combination of talent made it possible to screen a large number of insecticides and repellents, to select the more promising, to determine their toxicology, to explore the feasibility of their manufacture for military or civilian use and within a relatively short period of time to make adequate field tests of the selected products. Subsequent events have proved the worth of this approach to the problems of insect-borne disease. The nation now has within its grasp not only means to effectively control louse and flea-borne typhus fevers and the fly transmissions of the dysenteries but also improved methods for controlling malaria, leishmaniasis, dengue, pappataci fever and filariasis. Progress has been made in controlling mite-borne diseases, and a lead has been obtained on how to control plague. There must be a continuation and extension of these efforts, and soon it should be possible for human beings to live in all parts of the earth without fear of insect-borne diseases.

In the past it has been possible to control insects only in a limited way. This was due to the fact that when nonpersistent agents are employed it is necessary to repeat insecticidal work at intervals of not over five to seven days in order to destroy newly emerged broods that were not affected by previous work. In attempting to control or eliminate an insect from the environment, it is necessary to have a persistent insecticide. If the agent is nonpersistent, then persistency must be simulated by frequency of application. This method of attack not only kills the adult insects and larvae already present but also is a constant destructive agent for subsequently emerging adults, nymphs or larvae.

Early studies made by the Bureau of Entomology, U. S. Department of Agriculture, attempted to solve this problem by the use of antioxidants to stabilize pyrethrum preparations, the use of activators to increase the rate of kill and to decrease the lethal dose, the addition of more stable chemicals, such as rotenone and the thiocyanates These efforts were partially successful and antilouse powders were produced with insecticide persistency up to fourteen days if applied as a dust and up to three months if high concentrations were impregnated into a fabric. Less persistency of contact insecticidal action was obtained in other fields.

These results were considered a promising but not a satisfactory answer, consequently the search was continued. This ultimately led to the examination of the compound now commonly known as DDT (4,4′-dichlorodiphenyltrichloroethane). It was first synthesized by a German chemist in 1874 and was patented as an insecticide in Germany in 1934 It is a crystalline white solid with a tendency to agglomerate and cling to a surface As ordinarily obtained it is tasteless and possesses a faint aromatic odor of chlorbenzine. It is insoluble in water but soluble in oils and certain organic solvents. It is relatively stable chemically in the presence of light, heat and moisture.

In 1939, J R. Geigy, Inc. of Basle, Switzerland investigated its insecticidal properties for the control of clothes moths and certain agriculture pests. They also noted some of its residual insecticidal action after its application to a surface. During December of 1942 and early in 1943, studies conducted at the Bureau of Entomology, U. S. Department of Agriculture Laboratory at Orlando, Fla., confirmed the Swiss work and extended the information on the use of DDT as an insecticide with long lasting residual effect. This information was immediately applied to the development of materials and methods for the control of lice, mosquitoes, flies, fleas, sandflies, mites, bedbugs, cockroaches, clothes moths and many other insects of economic importance. Its limitations in the control of ticks and other arachnids were soon discovered.

As little work had been done on the toxicology of DDT for man and animals, extensive work had to be completed prior to its adoption by the armed forces. By June 1943 the Food and Drug Administration, the National Institute of Health and the Kettering Laboratory, University of Cincinnati, were able to supply sufficient information on the toxicology of the preparation to allow the armed forces to request its manufacture in large quantity. This was indeed fortunate, for with the world shortage of pyrethrum there was great need of a good insecticide. The principal ingredients required for its manufacture were alcohol and chlorbenzine. These items, although on the critical list, were available in quantity in the United States. Subsequently, sufficient DDT was manufactured, distributed and utilized by the armed forces to aid in the control of typhus fever in Europe, Africa, Japan and Korea, and of malaria in the Pacific, Mediterranean, African, Indian and Caribbean areas, as well as to contribute to the control of the dysenteries, dengue, sandfly fever and other insect-borne diseases encountered by U. S. troops. The materials and methods developed are applicable to civilian as well as military use. Thus the necessity of war has contributed materially to peacetime living.

In using DDT as an insecticide, it must be remembered that it is slow to act, with a knockdown varying from a few minutes to more than one hour; most insects showing evidence of DDT poisoning die, and its chief advantage over other insecticides is that on proper application to a surface it continues to be a potent contact insecticide for as long as three or four months. This latter property obviously has great significance in any insect control program.

Various means have been devised to apply DDT. These include oily sprays using solvents, such as kerosene; dusts utilizing inert diluents, such as talc; aerosols using gas under pressure for their formation; water emulsions made from a solution of 20 per cent DDT dissolved in a proprietary formaldehyde-containing soft soap plus a wetting agent; and wettable DDT sprayed from a water suspension. The object of all methods of application is to leave a residue on the sprayed area, and good insect control should not be expected unless the user adheres to this principle.

For the control of adult flies a residue of 100 to 200 mg. per square foot should be applied to surfaces where flies commonly rest, such as the sides of buildings, walls and screens. Such a residue is obtained when a 5 per cent DDT solution in kerosene is applied in a coarse spray to a surface in the amount that makes wetting evident. This same method of application is useful in the control of mosquito-borne diseases transmitted from man to man. The mosquito taking a blood feed usually rests on a nearby wall prior to or after the blood feed. Contact with a DDT-sprayed wall for twenty seconds to two minutes is usually sufficient for the insect to absorb fatal amounts of the compound.

DDT's value in the control of louse-borne typhus fever is due to the fact that when a dust or emulsion of it is applied to clothing that is not subsequently washed, it remains as an effective insecticide for a period of at least one month. Adult lice or nymphs are soon killed, and any lice that subsequently hatch or are picked up from other sources meet the same fate. Because of the ease of application and the long continued action, it is feasible to reduce the louse infestation of large populations to levels where typhus fever will not be transmitted. Because of its slow knockdown for lice, it is not recommended for treatment against crab lice and head lice. A combination of DDT and pyrethrums should be used for this purpose. Fleas can be controlled in human environments with the same methods utilized for lice if, in addition, the floors, including rugs, of all human habitations involved are sprayed with DDT. This procedure has great promise in the control of plague.

Sandflies can be controlled by a residual spray applied around the windows and doors of buildings. This acts as a lethal barrier for sandflies attempting to enter a building. For pest insects, such as the cockroach and bedbug, DDT gives the best control that has been obtained to date. This is due to the long lasting residual effect which continues to kill emerging nymphs that subsequently hatch from previously deposited eggs. This latter factor has been responsible for most of the failures with other types of insecticides.

With the demonstrable great toxicity of DDT for many species of insects, it should be obvious that toxicity for mammals would also exist. Nevertheless, in spite of its extensive use as an insecticide, no clear-cut cases of human poisoning due to DDT have been seen in the United States. Dr. Paul A. Neal of the National Institute of Health has expressed the opinion that in cases studied to date the toxic manifestations have been due to the solvent and not to the DDT itself. He emphasized that symptoms produced by solvents, either locally or systemically, set in rather promptly, whereas those symptoms produced by DDT develop only after a latent period of several hours.

An idea of the relative toxicity of DDT for laboratory animals can be gained from the fact that the lethal oral dose in olive oil varies from 240 mg. per kilogram of body weight for rats and 300 mg. for cats and rabbits to over 1,000 mg. for goats. Due to differences in the absorption and fat content of the animal, there is considerable variation in the size of the lethal dose for individual animals within a species. Young animals have been found to have increased susceptibility.

DDT in the form of a dry powder is nonirritating and apparently not absorbed through the skin, and its absorption in the gastrointestinal tract is variable, depending on the presence of fats or other solvents. It is capable of slow absorption through the skin if applied in oily solution. Animals that tend to lick themselves may get increased absorption by the ingestion of DDT materials applied to the fur or skin.

The symptomatology manifested by animals suffering from experimental DDT poisoning is characterized by hyperexcitability, nervousness, tremors, chronic convulsions and coma. The site of action in mammals appears to be in the central nervous system. The type of convulsion encountered in acute DDT poisoning resembles that seen in strychnine poisoning, in that it can be elicited by irritation and mechanical stimuli such as jarring. In sublethal amounts recovery is usually complete without residuums, and there appears to be no important lasting damage to any body tissue or organ. In both animals and man the organic chlorides of the urine have been found to be increased subsequent to the ingestion of DDT. The Division of Pharmacology, Food and Drug Administration, and the U. S. Department of Agriculture have shown that DDT is partially stored in the fats of the body and is gradually eliminated in bile, feces and urine in the form of 2,2 bis (p-chlorophenyl) acetic acid or other metabolites. It is also excreted in the milk, which may be of significance if DDT is used as an insecticide on forage crops. It must be pointed out that with reasonable agricultural control the likelihood of anyone ingesting toxic amounts of contaminating DDT are extremely small, and that dangers from DDT are probably much less than those from nicotine sulfate, arsenical insecticides, sodium fluoride or solvents such as carbon tetrachloride. In spite of this fact, it is extremely wise to be fully informed about the toxicology of DDT, so that maximum use can be made of this fine insecticide. The fund of knowledge on the toxicology of DDT is unique in that most of it was worked out before the product was released as an insecticide for the armed forces and the general public.

There is no specific antidote for DDT poisoning, but the use of phenobarbital has been extremely helpful in controlling DDT convulsions occurring in experimental animals. It is fortunate that toxicology studies of DDT have and are paralleling investigations on its insecticidal properties in all fields of insect control. The work of the Bureau of Entomology, U. S. Department of Agriculture, the Food and Drug Administration, the Public Health Service, The Fish and Wild Life Bureau of the Department of the Interior and the Chemical Warfare Service Laboratories at Edgewood Arsenal, Maryland, coupled with contracts and field work of the Medical Department, the Quartermaster Corps and the Corps of Engineers, the U. S. Army, the U. S. Navy and various civil agencies, have and are still adding to the store of information needed to properly exploit DDT for man's benefit.

CONCLUSION

From the data available on DDT (4,4′-dichlorodiphenyltrichloroethane), the following conclusions may be drawn:

1. Its outstanding property is that in proper concentration, in a dispersed state, it continues to be a potent contact insecticide for several months.

2. It is a weapon of major importance which can be used to solve many problems of insect control.

3. It is relatively safe from the toxicologic point of view, and cases of DDT poisoning in human beings are not likely to occur when it is used as a household insecticide.

PORPHYRIA WITH EPIDERMOLYSIS BULLOSA

Report of a Case of the Tardive Congenital Type with Demonstration of Latent Porphyria in a Sister of the Patient

LOUIS A. BRUNSTING, M.D.
and
HAROLD L. MASON, Ph.D.
Rochester, Minn.

Bullous eruptions simulating epidermolysis bullosa, in which the exposed surfaces are sensitive to light, occur in association with porphyria and may represent the presenting symptoms of the disorder. Turner and Obermayer[1] described such a case of epidermolysis bullosa, with melanosis and hypertrichosis as well, and in a detailed survey of the literature and a discussion of the chemistry of the problem, listed 14 similar cases. They also reviewed 200 cases of hydroa and found that in 86 instances of the more severe type, hydroa vacciniforme, there was associated porphyria.

Porphyria is recognized as that rare, familial, metabolic fault in which abnormal kinds and amounts of porphyrins, especially uroporphyrin, are excreted in the urine and feces. The disease may be latent or asymptomatic for years, with or without the characteristic coloration of the urine. Surveys of families in which porphyria occurs may disclose the presence of uropor-

phyrin or the colorless porphobilinogen in the urine of apparently normal persons. Porphyria finds clinical expression in various forms: The acute type with intermittent episodes of serious gastrointestinal or nervous symptoms; the congenital type, which may begin in earliest childhood with red urine, erythrodontia, photosensitive skin and sometimes visceral complications, and intermediate types, which may belong to one or the other. For a general review of porphyrins the reader is referred to comprehensive discourses on the subject.[2] Reports indicate that the syndrome of acute porphyria is more common than is generally supposed.[3]

It was in the investigation of the classic case of congenital porphyria of Petry that Fischer[4] in 1915 established the groundwork of our present knowledge of porphyrins. He found that the urine and feces contained porphyrins which were distinct from hematoporphyrin; the urinary porphyrin he named uroporphyrin, the fecal porphyrin, coproporphyrin. These compounds exist in nature in the form of isomers I and III, the identification of which depends chiefly on the determination of the melting points of their respective methyl esters. The porphyrin isolated from the urine by Waldenström, and probably erroneously identified as uroporphyrin III, predominates in cases of acute porphyria; much of it is present as the zinc complex.[5] In cases of acute porphyria, in the active or latent phase, porphobilinogen can be demonstrated in the urine by a simple test.[6] Uroporphyrin I has chiefly been identified with cases of congenital porphyria, and porphobilinogen is absent. Such distinctions are not clear-cut, however, for exceptions occur; in view of the recent work of Watson and his collaborators[7] it is doubtful that the type of clinical manifestation is dependent on the type of isomer excreted in the urine or feces.

Sensitivity to light occurs more commonly in the congenital types of porphyria than in other types. Waldenström[2b] emphasized that in his extensive experience with acute porphyria in Scandinavians he had not encountered any instances of congenital porphyria and while, in his cases, pigmentation frequently occurred, there had been no instance of photosensitivity. He reviewed the observations of others on cases in which bullous eruptions and abdominal colic appeared in conjunction with porphyria and concluded that they were examples of the congenital type which he termed "porphyria cutanea tarda." The cases presented by Merkelbach[8] and, recently, by Taylor and his associates,[9] in which bullous reactions simulating epidermolysis bullosa occurred in association with abdominal colics, suggest the syndrome of acute porphyria although porphobilinogen was not recognized in the urine, and the type of uroporphyrin was not identified.

Nesbitt and Watkins[3b] reported an instance of photosensitivity of the bullous and urticarial type in the case of a young woman 20 years of age who had classic symptoms of acute porphyria, abdominal pains, jaundice and psychotic behavior. The urine revealed large amounts of coproporphyrin and uroporphyrin, the latter largely as the zinc complex. Tests of the blood gave strongly positive reactions for porphyrins. Death occurred two years later, and at necropsy there was found extensive degeneration of the liver with decided pigmentation of the Kupffer cells, as well as a gross pinkish tinting of the costal cartilages.[10]

The recent literature on light-sensitive eruptions has been summarized by Epstein[11] in 1939 and by Stokes and Beerman[12] in 1942. In the chapter on photosensitization by porphyrins in Blum's[13] excellent monograph on "Photodynamic Action and Diseases Caused by Light," the author reviewed the many attempts that have been made to reproduce by artificial means the cutaneous lesions of hydroa and epidermolysis bullosa. Except for a few equivocal exceptions, these experiments have been unsuccessful. Various explanations have been offered to account for these failures. Hydroa and epidermolysis bullosa, with or without porphyria, possess a number of factors in common, one of which is the sensitivity of the skin to trauma. It has been suggested that either the porphyrins may affect such altered skin to make it sensitive to light or there may be an indirect effect due to light itself. Even in cases of pronounced porphyrinuria there may be few or no demonstrable porphyrins in the blood stream, and the skin may remain unaffected. Granted that there is a certain correlation between bullous eruptions, photosensitivity and porphyria in animals and in man, still it is not proved that the production of bullae on the exposed surfaces is due to the photodynamic action of porphyrins in the skin.

Little is known concerning the factors which may precipitate the syndrome of porphyria or influence its course one way or the other. In most instances of acute toxic porphyria, drugs of the sulfonmethane type have been incriminated. In diseases of the liver, such as cirrhosis or after poisoning caused by lead or by chronic alcoholism the excretion of porphyrins is decidedly increased in the urine and feces.[14] Attempts have been made to treat porphyria by the use of liver extracts, but these have not given convincing results.

Dobriner and his associates[15] reported a quantitative reduction in the excretion of coproporphyrin in 3 children with congenital porphyria who were given such therapy.

In this paper we wish to report a case of epidermolysis bullosa, melanosis and hypertrichosis in association with porphyria, presumably of the congenital type, in which the tardive cutaneous reactions appeared late in life as the presenting symptoms of the disorder. Latent porphyria was demonstrated in the case of the patient's sister, who was apparently normal in other respects.

REPORT OF CASE

A woman aged 58 was admitted to the Mayo Clinic on Nov. 3, 1944 because of a decline in health and vigor over a period of eighteen months. During this time there had been a loss of 40 to 50 pounds (18.1 to 22.7 Kg.). In the spring of 1943, a blistering eruption had appeared on the exposed surfaces of the hands and the ankles, and this had persisted off and on until the time of admission. It was particularly pronounced after exposure to the bright summer sunlight.

Previous to the present illness, the patient's general health had been good. Both parents were dead. Three brothers had died of tuberculosis and one of ulcers of the stomach; one sister was living and well. The patient had been married twenty-five years, and there were four children living and well. In 1916 the left ovary and tube and the appendix had been removed. Four years prior to admission, the menopause had occurred without incident.

(Subsequent information was obtained in regard to the past history of the patient. She had been subject to spells of depression and for some years had imbibed considerable quantities of alcohol.)

In February 1943 it was observed that the skin of the dorsa of the hands, the forearms and the dorsa of the feet and ankles would blister readily under slight trauma, a condition which was aggravated by exposure to the sun throughout the next several months. Always of fair complexion, the patient had noted a gradual darkening of the color of the skin, most intense on the exposed portions of the face and neck. About the same time, she became aware of a downy growth of hair on the cheeks and upper lip, and bristles appeared on the chin. On the dorsa of the hands, patches of whitish decoloration appeared, and there were accumulations of small, yellowish white particles under the surface of the skin.

In May 1944, subsequent to a short period of dizziness, there was observed a transient weakness of the right arm. There was occasional tenderness of the smaller joints of the hands and fingers and of the right ankle.

During the eighteen months previous to admission, there had been an increasing sensation of fatigue, anorexia and a sensation of rapid aging. The weight dropped from a normal level of approximately 168 pounds (76.2 Kg.) to a low level of 117 pounds (53.1 Kg.) in December 1943.

The patient was under observation in the clinic on three occasions, in November 1944, in April 1945 and in November 1945. The general physical examination did not reveal significant abnormalities except in the smaller joints of the hands and in the skin. The cardiovascular system was apparently normal; the blood pressure was 124 mm. of mercury systolic and 88 diastolic. Neither the liver nor the spleen could be palpated. Pelvic examination revealed no pathologic conditions.

The scleras were slightly injected and tinted a faint yellow color. Ocular fundi revealed normal disks; the retinal arterioles were narrowed slightly. The mouth was edentulous. The tongue was normal.

On first inspection, the features indicated a person older than the stated age. The hair was streaked with gray; there was general hyperpigmentation; the skin of the face and neck was somewhat purplish in hue and thickened in texture, and the normal markings were exaggerated. There was a downy fuzz on the skin of the cheeks and upper lip; over the chin there was a scattering of stiff bristles. The smaller joints of the hands were stiffened and the right hand could not be closed. There was some disability in movement of the right wrist, and there was a slight swelling of the left ankle. The skin on the dorsa of the hands showed a mild degree of vitiligo, and there was a scattering of milia over the knuckles. On the dorsa of the hands and feet there were remnants of large, denuded vesicles, not associated with erythema. Friction on the adjacent skin provoked a positive Nikolsky sign. There were a few small unruptured vesicles as well as excoriations on the ankles.

The preliminary laboratory tests were as follows: The routine urinalysis showed no significant abnormalities. The concentration of hemoglobin was 14.2 Gm. per hundred cubic centimeters of blood; erythrocytes numbered 4,490,000 and leukocytes 8,100 and 7,200 respectively per cubic millimeter of blood. The Kline flocculation reaction for syphilis was negative. A roentgenogram of the thorax revealed no abnormalities. Roentgenograms of both wrists and both hands disclosed no evidence of arthritis, but there was a mild degree of osteoporosis. The concentrations of urea and uric acid in the blood were normal. The sedimentation rate of the erythrocytes by the Westergren method was normal. The basal metabolic rate was —6 per cent. Examination of the stools did not reveal parasites or ova. Examination of the liver by the sulfobromophthalein test showed a mild degree of retention of dye, graded 1 (on a basis of 1 to 4, in which 1 designates the least and 4 the greatest retention). The serum contained 0.8 mg. of indirect bilirubin per hundred cubic centimeters; there was no direct reaction.

Preliminary diagnostic considerations centered about the possibility of subacute disseminated lupus erythematosus, dermatomyositis and epidermolysis bullosa. Because of the history of recurring bullae with trauma and of exposure to sunlight affecting the exposed surfaces of the extremities, the urine was examined for porphyrins. There was no previous intimation of discolored urine.

A twenty-four hour specimen of urine collected on Nov. 9, 1944, showed a reddish color which deepened on standing to a port wine hue. Tests for porphobilinogen were negative. There was strong primary fluorescence. The twenty-four hour specimen of urine, totaling 550 cc., contained 2.82 mg. of coproporphyrin, and 18.5 mg. of uroporphyrin. The ether-insoluble porphyrin showed absorption bands with maxima at 532 and 574 millimicrons, which are characteristic of uroporphyrin metal complex. Addition of hydrochloric acid caused these maxima to shift to 550 and 593 millimicrons. In 25 per cent solution of hydrochloric acid the maxima of uroporphyrin are given as 554 and 597 millimicrons.

The specimen of urine collected on Nov. 15, 1944 contained 2.0 mg. of coproporphyrin and 11.4 mg. of uroporphyrin. On Nov. 20 and Dec. 8, 1944 the urine was examined qualitatively. The color appeared normal. There was a definite but not a strong degree of fluorescence. The specimen of Dec. 8, 1944 was estimated to contain approximately 1 to 2 mg. of porphyrins.

The ether-insoluble porphyrin contained in the first specimen of urine was isolated and esterified, and the methyl ester was crystallized from chloroform-methanol. The first crop weighed 8.2 mg. A second small crop softened over a range of temperature and finally melted at about 210 C. A third crop of 0.48 mg. melted at 260 C. After recrystallization the first crop melted at 283-285 C. and was considered to be uroporphyrin I methyl ester. Grinstein, Schwartz and Watson[7a] gave a melting point of 284 C. for this ester.

Two stool specimens were examined and an ether-insoluble porphyrin (uroporphyrin) was isolated. The amount was too small for adequate purification. The melting point of the best crystals was about 210 C. Coproporphyrin appeared to be present in traces but could not be identified. A chloroform-soluble porphyrin was present, either deuteroporphyrin or protoporphyrin, or a combination of the two.

---

[15] Dobriner, K.; Strain, W. H.; Guild, H., and Locallio, S. A.: The Excretion of Porphyrins in Congenital Porphyria, J. Clin. Investigation 17: 761-764 (Nov.) 1938.

A twenty-four hour specimen of urine was examined for 17-ketosteroids and found to contain 1.3 mg., well below the limits of normal. No porphyrins were detected in the blood serum; there was no methemoglobinemia.

At this time the patient's sister presented herself for discussion of the problem. She was in her middle fifties and had always been in excellent health. Her complexion was blond, her hair was white and she stated that the patient and she, until 1942, had been of similar complexion. The difference in appearance of the two sisters was striking. The urine of the sister was examined on Nov. 20, 1944. It was of normal color but possessed a strong degree of primary fluorescence; the test for porphobilinogen gave negative results. Coproporphyrin, 1.6 mg. was present, as was an ether-insoluble porphyrin in an amount too small for quantitative determination. The ether-insoluble porphyrin was concentrated by adsorption on superfiltrol, and its absorption in 25 per cent solution of hydrochloric acid was determined. Maximal bands of absorption were found at 552 and 593 millimicrons. It was possible to prepare and crystallize the ester of this small amount of porphyrin. The methyl ester melted at 271 C., a fact which indicated that it was largely uroporphyrin I. The amount was too small for further crystallization.

At a later date, the patient's daughter, an apparently healthy young woman in her twenties, presented herself for examination. A twenty-four hour specimen of urine was examined and found to, contain normal amounts of coproporphyrin, but there was no primary fluorescence. There was no evidence of porphobilinogen.

EXPERIMENTAL DETAILS OF THE ANALYSIS OF URINE AND FECES FOR PORPHYRINS

I. The Patient.—Urine: One twenty-four hour specimen of *urine was obtained with a volume of 550 cc. After addition* of 60 cc. of acetic acid, it was extracted three times with 250 cc. of ether. The urine residue was adjusted to p_H 3.7 and allowed to stand for three days. The porphyrin which precipitated was filtered out and dried on the filter paper. It was removed from the paper with pyridine, which was then evaporated in a stream of air. The residue was suspended in dry chloroform containing a little methanol and treated with an excess of diazomethane in ether. The porphyrin dissolved quickly, which indicated a rapid formation of the methyl ester. After being allowed to stand overnight, the solvents were evaporated on the steam bath, and the residue was recrystallized *from chloroform-methanol. The first crop of 8.2 mg.* melted at 275-285 C. After a second recrystallization it melted at 283-285 C. (corrected), which is the melting point of uroporphyrin I. The second crop was extremely small and melted at about 210 C. The third crop of 0.48 mg. melted at 260 C.

Stool: Two stool specimens were combined and treated with acetone. The stool was then extracted repeatedly with methanol containing hydrochloric acid. After removal of the methanol under reduced pressure, the aqueous residue was allowed to stand overnight. It was then diluted and extracted with chloroform, which removed most of the porphyrin. The aqueous residue was neutralized to Congo red with sodium acetate and extracted with ether. The porphyrin in the ether was taken into 1 per cent solution of hydrochloric acid, and the acid solution was extracted with chloroform which removed all the porphyrin. This fraction was not studied further. The acetone extract of the stool was evaporated to dryness. The residue was taken up in water and extracted with ether and acetic acid. The aqueous residue was combined with the aqueous solution *remaining after extraction* with chloroform and ether, and the p_H was adjusted to about 2.7. After the aqueous solution had stood overnight the precipitate was filtered out, dissolved in 5 per cent solution of hydrochloric acid and again precipitated. It was then dried and esterified with diazomethane. The methyl ester was extremely difficult to crystallize, but a few crystals were obtained which melted at about 210 C. The properties of *this fraction* indicated that it was uroporphyrin, but there was too little to permit identification of isomers.

II. The Patient's Sister.—Urine: One twenty-four hour specimen of normal colored urine was available. The porphyrins were adsorbed on superfiltrol after the addition of hydrochloric acid and then eluted with dilute ammonia. The eluate was acidified to litmus with acetic acid and 20 cc. more of glacial acetic acid was added. After extraction three times with an equal volume of ether, the aqueous residue was adjusted to p_H 3.7. Since no precipitate appeared on standing, the solution was acidified, and the porphyrin again was adsorbed on superfiltrol and eluted with 2.5 per cent solution of ammonia. This time a precipitate appeared after adjustment of the p_H to 3.7 and allowing the solution to stand overnight. It was filtered out on a small pad of infusorial earth. The pad was then washed with a few cubic centimeters of pyridine, which dissolved the porphyrin. The pyridine was removed in a stream of air. The residue was leached with dilute hydrochloric acid, which dissolved the porphyrin and left considerable brown material undissolved. Sodium acetate was added to the hydrochloric acid solution until Congo red paper gave a blue gray color. It was then extracted twice with ethyl acetate, which removed all the porphyrin, leaving most of the brown color in the aqueous phase. The ethyl acetate was extracted twice with 5 cc. of 25 per cent solution of hydrochloric acid. After neutralization to Congo red with sodium acetate, extraction with ether failed to remove any porphyrin from the aqueous phase. Hydrochloric acid was added until the solution gave a blue gray color with Congo red paper. The porphyrin was then extracted with ethyl acetate. The solvent was evaporated, and the residue was esterified with diazomethane. Recrystallization of the ester twice from chloroform-methanol gave a few crystals which melted at 271 C. Since this melting point is higher than that of the Waldenstrom porphyrin, it was considered to be indicative of slightly impure uroporphyrin I methyl ester.

FURTHER CLINICAL COURSE

Based on these observations, a diagnosis of porphyria was made. This was considered to account for the systemic symptoms and the changes in the skin, including the picture of pseudo epidermolysis bullosa with apparent photosensitivity, milia, melanosis and hypertrichosis. In view of the tinted scleras and the slight evidence of hepatic dysfunction, a program was instituted similar to that which is advised in the treatment of cirrhosis. A diet was prescribed which was high in caloric and vitamin content, high in protein and carbohydrates and low in fats. Vitamin supplement of the B complex was added.

Tests were made of the skin of the forearms and back to determine evidence of photosensitivity. The skin of the back and forearms was exposed to erythema doses of radiation from four sources, quartz mercury vapor lamp, carbon arc lamp, infra-red Mazda bulb and natural sun. Exposure was made directly and through filtration including ordinary window glass and four selective spectral filters.[16] The result of these experiments indicated no abnormal reaction to light except a mottling in the areas exposed to the infra-red source with a faint erythema of the skin with the B carbons. The patient was later given measures of physical therapy to the hands for the distress in the joints. On exposure to mild radiant heat there was no untoward reaction of the skin.

Reexamination of the patient in April 1945 indicated an *improvement of general health. The color of the face was* somewhat lighter, there was good appetite, and there had been a gain of weight to 134 pounds (60.8 Kg.). There had been no further blistering of the skin under trauma or after exposure to the sun.

Examination of the urine revealed 3.32 mg. of uroporphyrin in a twenty-four hour specimen. The sulfobromophthalein dye test for hepatic function showed no retention of the dye.

Reexamination in November 1945 showed a still further degree of improvement in the hue of the skin. There had been no further episodes of bullous eruption. Examination of the urine showed no porphobilinogen; there were 2.16 mg. of coproporphyrin and 9.4 mg. of uroporphyrin in a twenty-four hour specimen. A test for hepatic function showed no retention of the dye.

[16] McLoughlin, C. J., and Krusen, F. H.: A Practical Skin Test for the Study of Photosensitivity, Proc. Staff Meet., Mayo Clin. **16**: 478-480 (July 23) 1941.

During the summer of 1945 there had developed episodes of mild, jacksonian-like attacks, involving first the lower extremities, and subsequently the right arm as well. At the same time, there were spells of transitory motor aphasia. Neurologic examination did not reveal any localizing signs to account for this disturbance. The blood pressure was normal; a roentgenogram of the skull was negative; the electroencephalogram revealed dysrhythmia. It was tentatively considered that the jacksonian episodes were on some obscure vascular basis, and a program of sedation was prescribed. Instead of barbiturates, the patient was given bromides by mouth, and a moderate degree of improvement ensued. In the course of several months on this regimen, the symptoms of jacksonian episodes improved, but there developed a transient episode of mental confusion and difficulty in walking, which was found to be on the basis of bromism.

COMMENT

Late in the course of the patient's examination, information came to us from an outside source that there had been a chronic overuse of alcohol for a number of years preceding the onset of the present illness. This was reflected in the evidence of disturbed hepatic function and decline in health and confirmed our decision to emphasize in the course of treatment those procedures which have been recommended for the protection of the liver in the management of hepatic cirrhosis.[17] Under this program there resulted amelioration of symptoms and improvement of the general health.

One may conjecture on the influence of alcoholism and hepatic dysfunction toward the precipitation of latent porphyria into the clinical phase of the disease, as in this case with symptoms of photosensitivity and epidermolysis bullosa, for the liver is concerned in the metabolism and excretion of porphyrins. Notwithstanding improvement of the general health of our patient, on several occasions during the course of a year a relatively large amount of uroporphyrin was found in the urine.

The predominance of uroporphyrin I and the absence of porphobilinogen, considered in the light of the symptoms reported, suggest strongly that this represents a case of congenital porphyria in which the disease had remained dormant until late in life. The presence of uroporphyrin I and increased amounts of coproporphyrin and the absence of porphobilinogen in the urine of the patient's sister, who exhibited no clinical symptoms of porphyria, support this view and bring out the familial aspects of the disease.

Failure to reproduce the cutaneous symptoms by exposure of the skin to artificial irradiation or by natural sunlight is consistent with the experience of other workers in this field.

SUMMARY

Cutaneous signs of epidermolysis bullosa, melanosis and hypertrichosis were the presenting symptoms in a case of porphyria, presumably of the tardive congenital type, occurring in a 58 year old woman who had hepatic dysfunction and a history of alcoholism. Latent porphyria was demonstrated in a sister of the patient. An ether-insoluble porphyrin identified as uroporphyrin I was recovered from the urine and, in small amounts, from the feces. Reactions of photosensitivity could not be artificially reproduced. The general health of the patient improved under an anticirrhotic regimen.

ABSTRACT OF DISCUSSION

Dr. Cleveland J. White, Chicago: The title of this excellent treatise with detailed case report is well chosen. While this paper leaves little for discussion, it does provoke a few clinical speculations. Porphyria is uncommon, but it behooves one to search more often for it, especially when such bullous lesions appear, especially on the exposed parts. This patient had bullous lesions; also the dorsal surfaces of the feet and ankles were affected. Their experiments with irradiation of various sources of ultraviolet rays producing no similar lesions shows that there may be additional factors besides the porphyrins of these types demonstrated to be the cause of the bullous lesions. These experiments, along with the findings of Blum and his associates, in hydroa vacciniforme show that the porphyrins apparently are not the photosensitizing agents involved in the production of skin lesions, as many previously thought was the case. It is known that the output of coproporphyrin type I is much increased in cirrhosis due to cinchophen, and similar drugs, also in hemolytic jaundice, pernicious anemia and congenital porphyrinuria. Type III is mainly increased in lead poisoning and in atropic and pigmentary cirrhosis of the liver. The supposed effect of uroporphyrin anuria in producing excessive sensitivity to light and producing skin lesions will have to be reevaluated. As well demonstrated, this is undoubtedly a case of congenital porphyria of the tardive type, the other two types having been well ruled out. An interesting feature, besides the epidermolysis bullosa type of lesions, is the presence of a widespread melanosis. It is rarely if ever seen in the congenital epidermolysis bullosa and was not found in a case recently studied. The association of hypertrichosis and melena is difficult to assay. I should like to ask Dr. Brunsting his opinion, whether he thinks they are incidental or probably a definite pair of this syndrome. The authors have further investigated the porphyrin problem by demonstrating uroporphyrinuria in her apparently normal sister, which suggests the familial element of this disorder. This finding of porphyrinuria in the case creates a stimulus to all to search in other cases, especially in bullous lesions if they lie on the unexposed parts of the body. This excellent presentation gives all of us an urge to study more dermatologic syndromes from this point of view.

Dr. Maximilian E. Obermayer, Los Angeles: I am particularly pleased with this report, which confirms the observations of Turner and myself published in 1938. The case reported by the authors is strikingly similar to that which formed the core of our report and to the 14 others which we were able to collect from the literature. The term porphyria cutanea tarda appears well chosen for this syndrome. Through the cooperation of Dr. Stephen Rothman and his staff at the University of Chicago School of Medicine I was enabled to collect some data about the present status of the patient whom we studied ten years ago. Her urine is still red and shows a concentration of 31 micrograms of coproporphyrin per hundred cubic centimeters, or about double the normal value. Detailed examinations for uroporphyrin were not carried out, but this substance was not identified on gross spectroscopy. The patient stated that her sensitivity to light had not changed but that she had learned to protect herself against the sun and has had only mild recurrences of the cutaneous symptoms in the last few years. Abnormal reactions to light still could not be elicited. The most interesting feature of the follow-up is the account of a severe psychotic episode which began in 1945; the patient is still under psychiatric treatment. I am inclined to interpret this psychosis and the jacksonian convulsions exhibited by the patient of Brunsting and Mason as late manifestations of porphyria. Neither the authors nor we were able to arrive at definite conclusions about the pathogenesis of the syndrome. In view of Turner's demonstration of the occurrence of physiologic porphyria in the fox squirrel, it seemed unlikely that actual hepatic disease is involved in the genesis of human porphyria. Brunsting and Mason have considered the possible etiologic role of hepatic dysfunction, and their conjectures are supported by the results of the British and South African investigations which Adler presented before the Royal Society of Medicine (Adler,

---

[17] Snell, A. M.: Portal Cirrhosis, California & West. Med. 63: 74-78 (Aug.) 1945.

A.: Solar Dermatitis in Adults, Proc. Roy. Soc. Med. **36**:284 [April] 1943). A wealth of experimental data appear to point toward a causal connection between hepatic damage and hypersensitivity to light. Cattle in South Africa acquire a disease characterized by hypersensitivity to light when they are allowed to feed on plants containing toxic substances which act on the liver. Similar sensitization was brought about experimentally by damaging the liver through ligation of the common duct. Further studies led to the discovery that absence of a substance which accompanies vitamin A is the critical factor in causation of the hypersensitivity. Liver cells always contain vitamin A, which is necessary for their normal function. The toxic influence of thyroxin, which leads to the disappearance of glycogen from the liver, can be successfully counteracted by the administration of vitamin A.

DR. ERVIN EPSTEIN, Oakland, Calif.: It should be stressed that congenital porphyrinuria is a potentially serious condition. I recall a woman aged 18 whom I saw in the hospital some years ago. She was in coma when brought in. There was no history available and the only findings were mild erythema of the chest and a Burgundy wine colored urine. Examination of this urine proved that she had porphyrinuria. She died within a couple of days. We were later able to reconstruct some of the history from her friends and members of her family. She had been in the psychiatric wards of the hospital a number of times. Each admission was for an acute episode of mental confusion. Each time dark colored urine was noted, but at no time were examinations made for porphyrins. The erythema of the chest was later found to be due to an ultraviolet light treatment given for a cold. That, of course, seemed to be the precipitating factor in this case.

DR. THOMAS S. SAUNDERS, Portland, Ore.: I should like to raise two questions. One concerns the production of hyperpigmentation and hypertrichosis: is that an indication of adrenal dysfunction? I think we must agree that the production of hyperpigmentation in a light-sensitive person is more or less a physiologically protective proposition. The other question: I wonder if it makes any difference what the light-sensitive patient eats. The textbooks all say he should eat a diet low in animal protein, yet Bommer makes the statement that a light-sensitive patient should avoid eating green leafy vegetables, reasoning by analogy that the chlorophyll in the vegetation would make him even more sensitive to light.

DR. LOUIS A. BRUNSTING, Rochester, Minn.: I will answer the last question first. I am not familiar with conditions of photosensitivity in human beings due to dietary factors, but in animals, especially in the sheep industry, it is well known that the ingestion of certain weeds produces not only a high degree of photosensitivity but severe hepatic damage as well. In our patient hypertrichosis and melanosis had developed to a degree where the patient's skin was in decided contrast to that of her sister, whereas normally the two had been of the same complexion. There was no evidence of dysfunction of the adrenal cortex; the urine contained normal levels of 17-ketosteroids.

Electrocardiographic Changes Following Tachycardia.—Striking electrocardiographic alterations may persist for a long period of time after an attack of paroxysmal tachycardia in individuals who do not have evidence of structural heart disease. These changes are most prominent following paroxysms of ventricular tachycardia and consist in depression of the ST segments, lowering or inversion of the T waves and prolongation of the QT interval. This phenomenon has not been generally recognized. . . . As postulated by Cossio, Vedoya and Berconsky, it is thought that the automatic focus which is responsible for the paroxysmal ventricular tachycardia retains some type of activity after the cessation of the tachycardia, influencing the electrical phenomenon to produce the abnormalities of the T waves, the ST segments and the QT intervals. This syndrome is not indicative of serious heart disease, for which it may be mistaken.—Smith, Leslie B.: Paroxysmal Ventricular Tachycardia Followed by Electrocardiographic Syndrome, *American Heart Journal,* August 1946.

Clinical Notes, Suggestions and New Instruments

MENINGITIS DUE TO ESCHERICHIA COLI

Streptomycin Therapy

WILLIAM P. SHIELDS, M.D.
Providence, R. I.

Meningitis due to Escherichia coli is a rare disease at the Charles V. Chapin Hospital. During the ten year period Jan. 1, 1936 to Jan. 1, 1946, 776 patients with meningitis of all types have been admitted to this hospital. During this period there were not any cases of meningitis due to Esch. coli.

Alexander[1] recently reported the first instance of treatment of this disease with streptomycin. The patient was a 19 year old soldier. The source of infection was probably a bacteremia secondary to a mixed type of osteomyelitis of the tibia. This patient recovered with no apparent sequelae. There have been reports of the use of the sulfonamides in this disease. Thompson and Quinn,[2] Rauch and Krinsky,[3] Hollis and Baty,[4] Barrett[5] and his associates, McLendon and Mitchell[6] and Strong and Edwards[7] have reported cases with recovery—a few of full recovery, but others with sequelae such as hydrocephalus and encephalopathy with atrophy of the optic nerve. The rarity of the following case, the mode of treatment and the satisfactory response make it appear worthy of publication.

* A differential cell count was not made. However, most of the cells were lymphocytes.

REPORT OF CASE

History.—M. D., a white male infant aged 5 weeks, was born in a hospital in Providence, R. I. on May 8, 1946. The delivery was normal. The child weighed 7 pounds and 7 ounces (3,374 Gm.) at birth. Shortly thereafter, the child was given an evaporated milk formula, to which a preparation of dextrin and maltose was added. On the tenth hospital day he was discharged, weighing 7 pounds and 9 ounces (3,430 Gm.).

From the outpatient department of the Charles V. Chapin Hospital.

The streptomycin was supplied by Merck & Co., Inc., Rahway, N. J., through the National Research Council, Chester S. Keefer, Chairman.

The infant was taken to his parents' home in West Warwick, R. I., and for the next three weeks seemed to do well, except that he had six or seven soft stools a day. Beginning with the fourth week, the formula was changed to a mixture of pasteurized milk and water, to which a preparation of dextrin and maltose was added. The child then began to have three or four formed stools a day. On June 14, at the age of 5 weeks, the mother noticed that the child was exceedingly warm and appeared irritable. The family physician who was called said that the child had a fever. Two days later the mother was alarmed by the rolling of the child's eyes and a profuse drooling of saliva from his mouth. During this time his appetite was good, and there was no vomiting. On June 18, the infant had tremors of all extremities, vomited once and appeared feverish and irritable. He was then brought to this hospital.

Physical Examination.—The baby appeared critically ill. The temperature was 99 F., the pulse rate 140 and the respiratory rate 40 per minute. The cry was lusty, and the bodily movements were vigorous. The skin was pale, the color was poor, and there was neither rash nor icterus. During the examination the child had a generalized convulsion of short duration. The skull was well formed, and the anterior fontanel was bulging. The eyes showed lateral nystagmoid movements, but strabismus was absent. The scleras were clear, the pupils were dilated and reacted well to light. The nose and ears were normal. The throat was not inflamed, and the oral mucosa did not display abnormalities. A systolic murmur, grade 2, was heard over the precordium, and a sinus arrhythmia was present. The lungs were clear, the abdomen was soft, and the liver was palpable. Neurologically, the child had generalized rigidity of the muscles of the lower extremities, back and neck and had a positive Kernig sign. Muscular paralyses were not evident.

A cisternal puncture was performed on admission, and 10 cc. of opalescent fluid under increased pressure was removed. In the accompanying table are summarized the data on the spinal fluid during the child's stay in the hospital.

Laboratory Data.—Examination of the blood revealed: hemoglobin 9.9 Gm. (68 per cent) by the Sahli method; red blood cells 4.2 million; white blood cells 12,150, with 60 per cent polymorphonuclears, 15 per cent small lymphocytes, 15 per cent large lymphocytes, 9 per cent monocytes and 1 per cent eosinophils. The red blood cells displayed a moderate to appreciable achromia. The urine was clear and gave normal results to the routine laboratory analyses. Culture of the blood on admission showed a pure growth of Esch. coli communior which was identical with the organism recovered from the spinal fluid. Cultures of material from the nose and throat were negative for hemolytic streptococci and diphtheria organisms. The Wassermann and Hinton tests were negative, and the blood group was type O.

Clinical Course.—The impression on admission was acute meningitis, type undetermined. Ten thousand units of penicillin were given into the basal cistern immediately, and a solution of 20 cc. of 5 per cent sodium sulfadiazine was given intravenously, followed by 150 cc. of isotonic solution of sodium chloride by slow intravenous drip. Sulfadiazine was then given orally in doses of 3.7 grains (0.25 Gm.) every six hours. During the evening of admission the infant had several severe twitchings but slept well and took the formula well.

The following day, June 19, the child's color was improved. Twitchings were absent, and the formula was taken well. A blood transfusion (75 cc. of citrated blood) was given on the following day, June 19. On June 21, 100 cc. of citrated blood was given, and this procedure was repeated on June 24. In the meantime, a gram-negative bacillus was found on culture of the spinal fluid, later identified as Esch. coli communior. Streptomycin treatment was instituted on June 20; 30,000 units were given into the basal cistern and 30,000 units were injected intramuscularly every three hours. The administration of sulfadiazine was discontinued as soon as the streptomycin therapy was instituted. This course of treatment was continued throughout the twelfth hospital day, for a total of ten days. The total parenteral dose was 2,630,000 units (intramuscularly) and, in addition, 300,000 units intrathecally. Untoward reactions were not apparent.

The patient took the formula well during the entire stay in the hospital. The weight on admission was 9 pounds and 2 ounces (4,139 Gm.), and on discharge it was 9 pounds and 9 ounces (4,337 Gm.). The circumference of the head was 15¼ inches (38.74 Cm.) during the stay in the hospital, and the anterior fontanel did not display bulging. The child was discharged to his parents on July 7, 1946, with 120 cells in the spinal fluid, which was negative, however, on culture. He was brought back for a check-up on July 10, at which time he was apparently well, and neurologic signs were absent. The cell count on the spinal fluid was 154, mostly lymphocytes, and organisms were not present on culture. The chemistry of the spinal fluid was normal.

Subsequent examination of the child has not shown evidence of sequelae or recurrence of the meningitis.

SUMMARY

A case of meningitis due to Escherichia coli communior and bacteremia in a 5 week old infant is reported. This child fully recovered without sequelae. Although this patient had received penicillin intrathecally and sulfadiazine both intravenously and orally at the onset of treatment, it is questionable whether there would have been such a rapid and satisfactory response without the streptomycin.

Streptomycin appears to be an important contribution to the treatment of meningitis due to Esch. coli.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

PENICILLIN OINTMENT.—A mixture of sodium or calcium penicillin in an ointment base composed of white petrolatum, liquid petrolatum, lanolin or any mixture of these with or without the addition of white or yellow wax and vegetable oil.

Actions and Uses.—Penicillin ointment is useful in the treatment of superficial infections of the eye involving the cornea, conjunctiva, meibomian glands and lacrimal sac caused by organisms susceptible to penicillin. It may be employed for topical application to burns of the skin to control infection. It may also be used for superficial infections of the skin such as impetigo, provided the infecting organism can be demonstrated to be penicillin sensitive.

Dosage.—Apply locally one or more times a day as the condition indicates. If indicated, supplement treatment with parenteral or oral administration of penicillin.

Abbott Laboratories, North Chicago, Ill.

Penicillin Calcium Ointment: 30 Gm. tubes. Each gram contains 1,000 units of penicillin calcium in white petrolatum, U. S. P.

Penicillin Calcium Ophthalmic Ointment: 4 Gm. tubes. Each gram contains 1,000 units of penicillin calcium in a base consisting of white petrolatum, U. S. P., 80 per cent and liquid petrolatum, U. S. P., 20 per cent.

E. R. Squibb & Sons, New York

Penicillin Calcium Ointment: 14.5 Gm. tubes. Each gram contains 1,000 units of penicillin calcium in a base consisting of beeswax, peanut oil, petrolatum and anhydrous lanolin.

Winthrop Chemical Co., Inc., New York

Penicillin Calcium Eye Ointment: 3.54 Gm. tubes. Each gram contains 1,000 units of penicillin calcium in a base consisting of white petrolatum, U. S. P., 60 per cent and liquid petrolatum, U. S. P., 20 per cent and lanolin anhydrous, U. S. P., 20 per cent.

PLANS FOR A RURAL HEALTH PROGRAM

The Committee on Rural Medical Service of the American Medical Association at its meeting in San Francisco on June 30 reported that thirty-one state medical societies had made progress toward establishing rural health committees and formulating medical society sponsored plans to improve rural health and to provide for voluntary prepayment against costs of illness. The Council on Medical Service and the Rural Medical Service Committee held additional meetings in September, emphasizing the interest of the medical profession in leading movements to improve the health services of rural communities. Significantly, committees formed by various rural organizations in the states to develop plans for health services have been interested in the point of view of the medical profession; leaders of national farm organizations are seeking the guidance of medical agencies. The major farm organizations are cooperating in the development of rural health programs. Through their committees they are initiating health educational programs and enrolment in prepayment plans on a local basis.

Joint meetings of rural health service committees of state medical societies and committees on rural health service of farm organizations have been reported by several states and are being planned by others. The discussions center around farm health needs, health facility surveys, medical personnel, an adequate public health and sanitation program, health education in the schools, dental health needs, health legislation, hospitals as memorials to war heroes, and what has been done for rural medical care in other states. Minimum standards for each type of health service need are being considered by state and national committees to serve as a guide, not to tell the local people what to do but to point out a way in which it may be done when once a decision has been reached.

The report from the physicians' rural health service committee of Minnesota states that, "if the presence of a physician in the community is to have the full effect in rural medicine, we must also have suitable homes for our rural families, balanced diet for the promotion of healthy growth and the maintenance of vigorous bodies. Knowledge of good living habits, instructions for expectant mothers, infant care, the home management of common ailments and first aid are most important and full confidence in and proper utilization of facilities for hospital and medical care that are at hand."

From Indiana comes the suggestion that hospitals might be extended into rural areas by inviting physicians in villages around hospitals to the courtesy staff. Thus they could attend staff meetings, bring their patients for consultation or diagnosis and care for their patients within the limits of their experience.

The problem of the farm family with low income in obtaining and paying for medical care might be solved by securing enrolment of farmers in a prepayment plan when income is relatively high. In some areas state and local welfare agencies may prepay the premiums of the indigent, and the state and local taxing units may be approached for part of the premium for low-income families.

STREPTOMYCIN-PROMIN THERAPY

In 1945 Smith and McClosky[1] of the National Institute of Health, Bethesda, Md., reported that streptomycin and promin when administered together, the one intramuscularly and the other orally, to guinea pigs infected with a human strain of tubercle bacilli exerted a chemotherapeutic action greater than what might have been expected from a simple summation of effects. This assumed synergic therapeutic action was afterward duplicated[2] by therapeutic tests on white rats, which are normally highly resistant hosts to tubercle bacilli.

Intraperitoneal or intravenous inoculation of human or bovine strains of tubercle bacilli into white rats usually results within a month in progressive proliferation of monocytes, forming aggregates of epitheloid cells, with a few multinucleated giant cells. These cellular aggregates are found predominantly in the lungs, liver and spleen. Tubercle bacilli multiply in great numbers in these cells without producing necrosis, caseation or other serious tissue damage. The whole process has litle effect on the general health until much of the normal lung is replaced by the epitheloid masses. This ultimately so impairs the normal respiratory function that the animal dies of asphyxia.

In the confirmatory tests, four groups of adult rats were each inoculated intraperitoneally with 5 mg. of virulent human tubercle bacilli. Each group consisted of 12 rats. Immediately after the inoculation, treatment was begun and continued as follows: group A, 50,000 units of streptomycin per kilogram injected intramuscularly once daily and promin fed in the daily diet at a level of 0.7 per cent; group B, promin fed in the diet at the same level but no streptomycin; group C, streptomycin given at the same level but no promin; group D, untreated controls. At twenty-eight to fifty-three days following inoculation the animals were killed by decapitation in sets of 4, 1 from each group. The left lobes of the lungs were finely emulsified. Smears, glycerin-egg slants and guinea pig inoculations were made with aliquot parts of each emulsion.

---

[1] Smith, M. I., and McClosky, W. T.: Pub. Health Rep. **60**: 1129 (Sept. 28) 1945.

[2] Smith, M. I.; McClosky, W. T., and Emmart, E. W.: Proc. Soc. Exper. Biol. & Med. **62**: 157 (June) 1946.

In group D (nontreated controls) 8 of the 12 animals showed positive smears, 11 developed tubercle bacilli on subcultures and all 12 developed tuberculosis on guinea pig inoculation (average severity 4.6 on the Smith scale[3]). In group C (promin treated) 9 of the 12 animals showed positive smears, 7 yielded positive subcultures and 9 gave positive inoculations in guinea pigs (average severity 3.1). In group C (streptomycin treated) only 2 rats gave positive lung smears, 8 positive subcultures and only 7 positive inoculations in guinea pigs (average severity 3.8). In contrast, group A (streptomycin plus promin) showed no positive lung smears, only 3 of the 12 members gave positive subcultures and there were only 5 positive guinea pig inoculations (average severity 0.7).

Summarizing his results, Smith concludes that under his selected experimental conditions treatment with promin alone was without beneficial effects. Treatment with streptomycin alone resulted in negligible therapeutic effects. Combined treatment with streptomycin and promin resulted in a sterilization of 41.6 per cent of the inoculated rats and an 85 per cent reduction in the number of viable (or virulent) tubercle bacilli in the remaining (58.4 per cent) members of the group.

A theory has not thus far been suggested to account for this presumable synergic therapeutic action. Whether or not the combined therapy would be equally effective in later intracellular stages of experimental tuberculosis in rats has not yet been determined.

HEALTH AND PHYSICAL FITNESS

With the establishment of the Health and Physical Fitness Project in its Bureau of Health Education, the Association takes another step forward in its effort to contribute to the promotion of health. Health and physical fitness are important even though the popular interest in them has considerably diminished with the end of the war. The Board of Trustees early in 1946 authorized the establishment of a health and physical fitness project in the Bureau of Health Education to work under the supervision of the American Medical Association Committee on Health and Physical Fitness.

The project will include the health and fitness problems of the preschool child, the school child, the college students, the adult, both rural and urban, and the industrial worker. Though the committee contemplates cooperation with all other health agencies working toward health improvement in home, school, industry and community, it has expressed the belief that it is first in the schools and second in industry that the most immediate and most practical approach to the problem lies. The efforts of the consultants in the project will therefore be directed primarily to these fields.

The committee will not attempt to set up any master plans or "ideal" health programs and then attempt to procure their widespread adoption in the schools and industries of all types and sizes. Rather it is the plan to accumulate source files on the varied health programs now in use with the purpose of making both reports on these programs and the advice and counsel of the two consultants available on invitation to boards of health, boards of education, employers, employee groups, medical societies and women's organizations.

This project is in a sense a continuation of the work carried on by the Association in conjunction with government agencies and other interested groups during the late war. Including the project in the total health education program of the Association and staffing it with a physician who has had wide experience in health education and an educator experienced in the health and physical education fields will give it a permanence and a practicability lacking in the previous organization.

TOMOGRAPHY IN THE DIAGNOSIS OF LUNG CARCINOMA

Grossmann[1] in 1935 described an apparatus with which he was able to demonstrate clearly pulmonary abnormalities not well shown by other radiographic means. The tomograph has steadily gained new advocates, particularly in England. Roentgenograms of a selected plane or stratum of the patient's body are accomplished by moving the tube and the film during the exposure in such a manner that the images of objects in the selected plane occupy the same positions on the film, while the images of objects in planes above or below that plane are blurred by the movement.

Recently Hartley,[2] in a review before the Section on Radiology of the Royal Society of Medicine, made a strong plea for this method of examination of chest lesions, especially when the diagnosis lies between primary carcinoma of the lung, mediastinal tumor or mediastinal metastasis. In these situations early diagnosis becomes more imperative as the possibilities of cure or alleviation by radiotherapy or surgery increase. These two therapeutic methods demand accuracy in diagnosis, the former in order to plan the radiation dosage, the latter in order to decide the question of operability.

[1] Grossmann, G.: Tomography, Fortschr. a. d. Geb. d. Röntgenstrahlen, **51:** 61 (Jan.), 191 (Feb.) 1935.

[2] Hartley, J. Blair: Tomography in the Diagnosis of Lung Carcinoma, Proc. Roy. Soc. Med. **39,** July 1946.

The demand for more accurate methods at the Holt Radium Institute arose from the fact that primary carcinoma of the lung referred for treatment multiplied 3.3 times from 1940 to 1944, and the number of cases of malignant disease of the mediastinum multiplied 2.5 times. The demand arose also because the established diagnostic method, bronchography using lipiodol, was contraindicated; the therapists objected that treatment was already difficult without introducing the factor of an unknown quantity of iodine within the lung; second, it was recognized that bronchoscopy had limited value in that some carcinomas lie in situations not visible or reachable by the bronschoscope; third, it was necessary to localize the treatable lesions in depth and, if possible, in extent.

Although the tomographic unit used in these investigations was the same simple and primitive unit used by Hartley's predecessor, the late E. W. Twining,[3] it was of great value both to the diagnostician and to the radiotherapist. The device was valuable in demonstrating whether one was dealing with carcinoma of the obstructing or ulcerating type or whether the lesion was extensive and of the peribronchial infiltrating variety, in confirming the obstruction of a bronchus and in demonstrating its probable site of origin and in demonstrating the size or depth of a carcinoma already diagnosed and the true nature of lesions incorrectly diagnosed. It was exceedingly useful as an aid in determining whether changes found in the chest picture during the follow-up period were due to recurrence of the treated lesion or to mechanical deformities resulting from fibrosis, which in turn might result from treatment.

Tomography has certain limitations. It does not necessarily indicate the exact nature of the lesion. It is frequently not reliable in distinguishing between how much of the lesion shown in a routine roentgenogram is due to malignancy and how much to infection. It does not easily demonstrate early lesions in the lungs; in fact, they may be missed; here improvements in technic are required. Tomography cannot replace routine radiography; it can be really satisfactorily carried out only after study of and with measurements obtained from both the posteroanterior and the lateral views. Nevertheless, as Hartley concludes, its value is not adequately realized, and it should replace lipiodol bronchography when the case is likely to be one of carcinoma of the bronchus or when radiation therapy is indicated.

Current Comment

POSTGRADUATE EDUCATION IN PSYCHOSOMATIC MEDICINE

An experimental graduate course was recently given to determine whether general practitioners can be *taught to practice in their offices the kind of medicine* psychoneurotic patients need. This course was sponsored jointly by the Commonwealth Fund and the Division of Postgraduate Education of the University of Minnesota and was held at the Center for Continuation Study of the University of Minnesota.[1] Two weeks was considered adequate for instruction without depriving the busy physician of too much of his time. The teaching staff was drawn from the ranks of younger psychiatrists, most of them with military experience. The student group consisted of twenty-five physicians representing the practice of medicine under varying conditions in communities of assorted size chiefly in Minnesota and neighboring states. Instruction was both didactic and clinical. After the course had been completed the following specific goals were defined:

1. To give the doctor a feeling of the dynamic qualities and the value of the doctor-patient relationship.
2. To introduce him to broad patterns of human motivation and to the common causes and backgrounds of emotional disturbance.
3. To lead him to think in terms of the relation between emotional disturbance and illness.
4. To teach him easily understandable methods of therapy so that he can treat a share of such illness.
5. To give him some knowledge of more malignant conditions so that he may refer them to specialists.

Careful analysis by both students and instructors at the end of the course furnished evidence that this type of graduate education had been valuable in a practical sense.

DECLINE IN INTELLIGENCE

Several studies have indicated that there is an average of a two or three point decline in intelligence (I. Q.) in each generation. According to Thomson,[1] it is impossible to say how much of this may be due to heredity and how much to environment. The theory of the decline is, of course, based on present methods of intelligence testing, but these, like other scientific technics, are subject to change. The decline, if true, may be due to the differential birth rate, families of higher intelligence ratings on the average having fewer children than those with low ratings. The subject is important enough to warrant intensive study. Thomson urges that actual measurement of two successive generations be made and that all who are in a position to facilitate such experiments exert themselves in this direction.

ORGANIZATION SECTION

Official Notes

MEETING OF EXECUTIVE COMMITTEE OF COUNCIL ON MEDICAL SERVICE

September 18, 1946

The meeting was called to order by the chairman, Dr. E. J. McCormick. Those present were Dr. James R. McVay, Dr. A. W. Adson, Dr. Louis H. Bauer, Dr. Joseph S. Lawrence, Thomas A. Hendricks, secretary, George W. Cooley, assistant secretary, Jay C. Ketchum, Howard O. Brower, L. S. Kleinschmidt and Frank G. Dickinson, Ph.D., director, Bureau of Medical Economic Research. Others present at intervals during the meeting were J. W. Holloway Jr., director, Bureau of Legal Medicine and Legislation; T. V. McDavitt, Bureau of Legal Medicine and Legislation; Dr. C. M. Peterson, secretary, Council on Industrial Health; Dr. John H. Fitzgibbon, and Dr. C. W. Roberts.

Relationship of Council to Associated Medical Care Plans.—Dr. McCormick and Dr. Adson gave a report of a joint meeting of Council representatives and officers of Associated Medical Care Plans. The Council discussed the financing of A. M. C. P., the location of its headquarters, the function it should assume and the degree of participation by the Council in policy control. In view of the meeting of plan executives set for October 4-6 it was voted that any further action on the relationship between the Council and A. M. C. P. be deferred until a later date.

The Seal of Acceptance.—Applications for the Seal of Acceptance were read and discussed. The following plans were added to the original nine plans:

Physicians Association of Clackamas County, Oregon.
Hospital Service Corporation, Alabama.
Hospital Service of California.
Florida Medical Service Corporation.
Genesee Valley Medical Care, New York.
Hospital Saving Association of North Carolina.
Oklahoma Physicians Service.
Coos Bay Hospital Association, Oregon.
Pacific Hospital Association, Oregon.
Klamath Medical Service Bureau, Oregon.
Group Medical and Surgical Service, Texas.
The Dallas County Medical Plan, Texas.
Surgical Care, Inc., Virginia.
Medical Surgical Service, Inc., West Virginia.
Marion County Medical Service, Inc., West Virginia.
Medical-Surgical Care, Inc., West Virginia.
West Virginia Medical Service.

Joint Meeting with Insurance Company Representatives.—Mr. Hendricks reported on a meeting with representatives of insurance associations.

Two committees suggested at the meetings were approved by the Council and the following appointed to serve as Council representatives: 1. Committee on Cooperation: Dr. A. W. Adson, chairman; Dr. James R. Miller; Lester Perry; ex officio members: Jay C. Ketchum, Frank Dickinson, Ph.D., and Howard Brower. 2. Committee on Rural Enrolment: Dr. James R. McVay, chairman; Dr. F. S. Crockett, and L. S. Kleinschmidt. Ex officio member, Frank G. Dickinson, Ph.D.

Authorization was given to make contact with the Blue Cross Commission and/or the American Hospital Association, requesting that representatives be appointed to serve on both committees.

Taft Bill.—The Council discussed the Taft bill, considering ways and means of evaluating the bill. A letter to the state medical societies asking for suggestions was authorized, with a report on the answers to be compiled for the next meeting. Letters from California and Washington were read and discussed.

United Mine Workers Health Fund.—Mr. Hendricks gave a report on the United Mine Workers Health Fund and the meeting in Williamson, W. Va., with the Mine Physicians' Group. A vote of commendation was extended to Dr. Walter B. Martin for his excellent work on the bituminous coal situation. It was suggested that a Council representative join one of the navy field teams in inspecting the coal mine areas. Dr. George Easley of Williamson, W. Va., spoke informally to the Council on the medical care situation in the coal mines. He was commended and was asked to keep the Council informed on future developments.

Rural Health.—The Council read and discussed the recent News Letter on Rural Health. It was suggested that similar letters might well be set up for other points of the Ten Point Program.

Mr. Hendricks introduced a new member of the Council staff, Mr. L. S. Kleinschmidt, who is to concentrate on rural medical care programs. Attention was called to the suggested program for rural participation in prepayment medical care plans, and the Council members were asked to become familiar with it for discussion at the next meeting.

Co-Op Movement.—Mr. Hendrick gave a report on the "Co-Op" meeting in Two Harbors, Minn. There was discussion as to the attitude of organized medicine on this movement. No action was considered advisable until further information could be developed.

Hill-Burton Bill.—The Council discussed a possible program with reference to the Hill-Burton bill. Dr. John Fitzgibbon and Dr. C. W. Roberts, members of the Board of Trustees, brought the thoughts of the Trustees on this matter to the Council. In general it was believed that the Council should provide the state medical societies with basic principles and policies to be followed in carrying out the provisions of the bill. Specifically, the Council was requested to prepare such recommendations for the House of Delegates meeting in December. The Council authorized a special News Letter to be sent out on the subject.

Miscellaneous Activities.—Debate Handbook: Handbooks on Compulsory Sickness Insurance: Mr. Cooley presented the final proofs of a new brochure entitled "Voluntary Health Insurance vs. Compulsory Sickness Insurance." This brochure is to be sent out in cooperation with the National University Extension Association as a part of the material for use by students in this year's debates. Over eight thousand requests have already been received, with more coming in daily. Several suggestions were made, and the proof was approved.

A Motion Picture: The Council authorized investigation into the possibility of either making or obtaining a movie showing the progress of medicine or of the prepayment plan movement. This would be made available to meetings of lay groups.

Speakers Bureau: The Council is organizing a program designed to develop speakers on various subjects of popular interest. Contact will be made with the state and county medical societies to find out the extent of such programs and get information for possibilities of some sort of correlation.

Washington Office: Dr. Lawrence spoke briefly on the Legislative Reorganization Act and on the new bill requiring the registration of lobbyists. He pointed out that although the Social Security Board was abolished the personnel, including Mr. Altmeyer, was transferred to the Federal Security Agency.

National Health Congress: There was considerable discussion as to the next moves to be made in correlating the efforts of the state and local health councils. It was decided to call a general meeting at the time of the House of Delegates meeting or the Secretaries' Conference.

American Cancer Society: Dr. McCormick read a letter from the American Cancer Society concerning the problem of diagnostic clinics. The matter was referred to Drs. Bauer, Miller, McGoldrick and McCormick with authorization to attend a meeting of the American Cancer Society in New York as Council representatives.

Rating Committee: The Council reviewed the work done to date on the schedule of relative values. In view of the joint committee work of the Council and the insurance associations, it was felt that the schedules should be completed as soon as possible.

RESOLUTIONS TO BE PRESENTED TO HOUSE OF DELEGATES

NOTE.—These resolutions are published in accordance with a request of the House of Delegates to the effect that resolutions to be presented before the House of Delegates be published thirty days before the House of Delegates is to convene in session

These two resolutions were adopted by the Utah State Medical Association:

Resolution on Rich Report

WHEREAS, The American Medical Association has had a complete and presumably competent survey of its public relations made by the Rich Associates, and

WHEREAS, The report of the Rich Associates apparently contains rather sweeping recommendations; and

WHEREAS, The contents of this report are unknown to the House of Delegates of the American Medical Association in spite of the fact that said House is the policy making body of the American Medical Association, and

WHEREAS, It is believed to be unwise for the House of Delegates to approve changes in the American Medical Association without knowledge of what it is that it approves, be it

Resolved, That the delegate to the American Medical Association is hereby instructed to take such action in the House of Delegates of the American Medical Association as will result in the members of that House becoming informed as to the contents of the so called Rich report of the Rich Associates

Resolution on Referring All Business to Reference Committees

WHEREAS, At the last meeting of the House of Delegates of the American Medical Association numerous matters were referred to the Board of Trustees as a reference committee, and

WHEREAS, At least one question was referred to the Judicial Council as a reference committee, and

WHEREAS, The By Laws of the American Medical Association clearly set forth the constitutional manner of appointment and duties of the reference committees of the House, and

WHEREAS, It appears improper that a standing committee of the Association should act as a reference committee to review its own actions; be it

Resolved, That the delegate to the American Medical Association is hereby directed to take such action in the said House as will result in all business of the House of Delegates being referred to the reference committees of the House in accordance with the By Laws of the American Medical Association.

Resolution on Fees from Insurance Companies

The following resolution was passed by the House of Deleates of the Tennessee State Medical Association:

Resolved, that it is the sense of the Tennessee State Medical Association in meeting assembled that we deplore the injustice of the insurance companies of America toward the members of the medical profession in their failure to raise the five dollar fee paid for medical examinations for more than seventy five years This rank unfairness is accentuated by the fact that the entire financial structure of life insurance is erected and its solvency based on the integrity and professional ability of the examining physician Moreover, this flagrant violation of fair practice on the part of all life insurance companies is made more glaring by the fact that no account is taken of the increased cost of medical education, medical equipment and medical expenses, including transition from the horse and buggy to the automobile age

Washington Letter

(From a Special Correspondent)

Oct. 28, 1946.

Global Control of Venereal Disease Advocated

Two U. S. Public Health Service officials, Dr. J. R. Heller, chief of the venereal disease division, and Dr. R. A. Vonderlehr, former chief who is now public health director in Puerto Rico, have written a book, "The Control of Venereal Disease," which proposes global control through closer international cooperation, a universal system of diagnostic service, worldwide organization of free clinics and global headquarters for the exchange of information

Hospital Deficiencies Cited by Dr. Claude W. Munger

Dr. Claude W. Munger, co-author of the Metropolitan Health and Hospital Survey, which accused Washington, D. C., hospitals and medical care of many shortcomings, reiterated that the city's hospitalization requirements were "crying aloud for solution." He joined with Admiral Ross T. McIntire, Surgeon General of the Navy, and Major Gen. U. S. Grant 3d, chairman, in an appeal for support of the George Washington University drive for $925,000 for its new hospital.

Nurses Who Died in Europe During World War II to Be Honored

The sixteen army nurses who died through enemy action in the war were honored at ceremonies Sunday in the amphitheater of Arlington National Cemetery. Major Gen. Norman T. Kirk, Surgeon General of the Army, introduced Secretary of War Patterson, who paid tribute to the war service of all enlisted nurses. In addition to the sixteen who died through enemy action, 180 army nurses died of natural causes while on duty.

George Washington University to Conduct Research in Anesthesia

Dean Walter A. Bloedorn of George Washington University School of Medicine reported here, coincident with the one hundredth anniversary of anesthesia, that a $20,000 grant had made possible the first major research in anesthesia ever conducted in Washington. Radioactive isotopes will be used in research when equipment such as the Geiger counters and radioactive materials become available

President Truman Honors Egyptian Undersecretary of Health

President Truman has presented to Dr. Ali Tewfik Sousha Pasha, Egyptian undersecretary of health, the Medal of Freedom with Silver Palm for research on typhus and other tropical diseases for the U. S. Navy during the war. The medal was presented at Cairo, Egypt, by naval attaché Capt. T. J. Carter in behalf of the President

Coming Medical Meetings

American Medical Association House of Delegates Supplemental Session, Chicago, Dec. 9-11. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Conference of State Secretaries and Editors, Chicago, Dec. 7-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Allergy, New York, Nov. 25 27. Dr. Karl D. Figley, 316 Michigan St., Toledo 2, Ohio, Secretary.

American Academy of Dermatology and Syphilology, Cleveland, Dec. 7 12. Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, N. Y., Secretary.

American Academy of Pediatrics, Pittsburgh, Nov. 13-16. Dr. C. G. Grulee, 636 Church St., Evanston, Ill., Secretary.

American College of Surgeons, Cleveland, Dec. 16 20. Dr. Dallas B. Phemister, 40 E Erie St, Chicago 11, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Nov. 14. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 1, Conn, Secretary.

American Public Health Association, Cleveland, Nov. 12-14. Dr. R. M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Society of Anesthesiologists, New York, Dec 12. Dr. Curtiss B. Hickcox, 745 Fifth Ave, Room 1503, New York, Secretary.

National Society for the Prevention of Blindness, New York, Nov. 25-27. Mrs. Eleanor Brown Merrill, 1790 Broadway, New York 19, Executive Director.

North Central Medical Conference, St Paul, Nov. 10 Mr. R. R. Rosell, 493 Lowry Medical Arts Building, St. Paul, Secretary.

Post Graduate Medical Assembly of South Texas, Houston, Dec. 3-5. Dr. M. B. Stokes, 229 Medical Arts Bldg., Houston, Secretary.

Puerto Rico, Medical Association of, Santurce, Dec 13-15. Dr. Rafael A. Vilar, P. O. Box 3866, Santurce, Secretary.

Radiological Society of North America, Chicago, Dec. 1-6. Dr. Donald S. Childs, 607 Medical Arts Bldg, Syracuse 2, N. Y., Secretary.

Society of Surgeons of New Jersey, Newark, Nov. 20. Dr. Walter B. Mount, 21 Plymouth St., Montclair, Secretary.

Southern Medical Association, Miami, Fla., Nov. 4-7. Mr. C. P. Loranz, Empire Bldg., Birmingham 3, Ala., Secretary.

Southern Surgical Association, Hot Springs, Va., Dec. 10-12. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Western Surgical Association, Memphis, Tenn., Dec. 5-7. Dr. Warren H. Cole, 1853 W. Polk St., Chicago 12, Secretary.

GOVERNMENT SERVICES

ARMY

FIRST MEETING OF THE SOCIETY OF U. S. MEDICAL CONSULTANTS

The first meeting of the Society of United States Medical Consultants of World War II was held at the Army Medical Center, Washington, D. C., on October 18. The society is composed of former medical officers, now returned to civilian life, who were consultants for the Army Medical Department in World War II. The group has formed this association under its own initiative to further the advance of the medical profession in the United States, with the particular objective of establishing close liaison with army medicine. Its plans are in the formative stage as yet, and one aim of this meeting was to set up a procedure which will aid in carrying out the objectives.

The meeting was opened by an address by the president of the society, former Brig. Gen. Elliott C. Cutler of Harvard University. Major Gen. Norman T. Kirk then paid tribute to the men whom he considers to have been highly instrumental in the record established by the Medical Department during the war, with its exceptionally low death and disease rates.

Eli Ginzberg, Ph.D., former chief of resources analysis, Office of the Surgeon General, and now professor of economics at Columbia University, analyzed certain problems coped with by the Medical Department during the war, the various methods tried and those which proved successful. He called particular attention to the achievement of the medical regulating officer, through whose offices flowed the assignment of patients at the rate of 20,000 a day who were sent to hospitals according to their type of injury or disease. Comments were freely made from the floor by the keenly interested audience, numbering about ninety, who had traveled from points over the country to attend the meeting in spite of the local hotel strike.

Major Gen. W. S. Paul, director of personnel administration, G-1, explained how the revised organization chart of the Army cleared out many barriers to enable the technical services to function at an optimum.

Luncheon at the Officers Club was followed by a closed afternoon session, attended only by members, for the discussion and ratification of the constitution and other business matters. New officers were elected as follows: president, Dr. Walter Bauer, Massachusetts General Hospital, Boston; vice president, Dr. Frank B. Berry, New York; secretary, Dr. Brian Blades, George Washington University Medical School, Washington, D. C.; treasurer, Dr. Donald M. Pillsbury, Department of Dermatology and Syphilology, University Hospital, Philadelphia, and a committee of four counselors, Dr. William S. Middleton, University of Wisconsin Medical School, Madison; Dr. Glen R. Spurling, University of Louisville, Ky.; Dr. Douglas A. Thom, Boston, and Dr. W. B. Parson, Presbyterian Hospital, New York.

A breakdown of specific services consultations constituted the Saturday morning program, with meetings held in various conference rooms in the hospital. Arrangements for the Saturday morning meetings were under the direction of former Brig. Gen. Hugh J. Morgan for the medical group, former Brig. Gen. William C. Menninger for the neuropsychiatric group and former Col. Brian Blades for the surgical group.

AIRBORNE MEDICAL COMPANY AWARDED THE CROIX DE GUERRE

The French military attaché in the United States, Lieut. Gen. Maurice Mathenet, and members of his staff flew from Washington to Fort Bragg, October 17, where fifteen units of the famous 82d Airborne Division were decorated with the Fourragère of the French Croix de Guerre. Among these units was the 307th Airborne Medical Company. The units decorated were cited for two separate actions in Normandy: one on June 5-6, 1944, the night before the D day invasion of France in the vicinity of Ste. Mère Eglise, and the other from June 6 to June 20 in and around le Merderet, la Douve, St. Sauvuer-le-Vicomte and Etienneville. The citations were signed by the head of the provisional government of the republic of France. The French fourragère is predominantly green and is worn on the left shoulder. The entire 82d Airborne Division had already received the Military Order of Willems from the Netherlands and the fourragère of the Belgian Croix de Guerre.

The Distinguished Unit Citation had previously been awarded by the War Department to the 307th Airborne Medical Company of the 82d Airborne Division for extraordinary heroism and outstanding performance of duty in the initial assault on the coast of Normandy on June 6, 1944. This unit landed by glider in the face of artillery, machine gun and antiaircraft fire, and almost without rest or pause for forty-eight hours its officers and enlisted men gave the utmost of their skill and will in caring for the wounded.

SOLDIERS' PREFERENCES FOR EMERGENCY FOOD ITEMS

The Quartermaster Corps inquired of 9,691 combat soldiers of World War II to name the items they would prefer in an emergency ration to be used if they were cut off from supply and could eat only the food they carried with them.

Their choice of items in order of frequency was coffee, cigarets, biscuits, crackers, candy, chewing gum, cheese, sugar, bacon and eggs or ham and eggs, frankfurters and beans, and meat and beans. All these men had eaten combat rations, and all of them had been awarded the Combat Infantry Badge.

When asked about the K ration items, which they consumed most completely, chewing gum drew 87 per cent of the favorable answers, caramels 85 per cent, candy bars 82 per cent, coffee 76 per cent and ham and eggs 68 per cent.

When asked about the C ration items they used most completely, 85 per cent of the men said chewing gum and 83 per cent caramels, and then in order candy coated peanuts, chocolate drops, frankfurters and beans, coffee, cocoa and fudge. Twenty-five per cent ate almost none of the beef stew. The fruit powders ran low in the lists.

Concerning the type of tobacco other than cigarets which they preferred in their PX rations issued at the front, 39 per cent went for pipe tobacco, 30 per cent for cigars, 20 per cent for cigaret tobacco and 10 per cent for chewing tobacco. Thirteen per cent of the men said that they did not smoke cigarets.

DELAY SEPARATION OF NURSES PENDING CLOSING OF HOSPITALS

Major Gen. Norman T. Kirk, the Surgeon General, announces that army nurses in category III on duty in hospitals scheduled for closing by December 31 will not commence their terminal leave until the hospital closes. Other category III nurses who would ordinarily commence terminal leave November 1 may be retained temporarily but must be relieved from active duty by December 1. In each instance in which a category III nurse is retained on active duty in a hospital slated for closing, her terminal leave must begin not later than December 31.

Army general hospitals scheduled for closing by December 31 are Halloran, Staten Island, New York; Bruns, Sante Fe, N. M.; Mason, Brentwood, Long Island, N. Y., and Wakeman, Camp Atterbury, Indiana. Moore General Hospital, Swannanoa, N. C., will close November 15.

With 75,000 patients in army hospitals throughout the world and a nursing shortage possible because of lowered discharge criteria announced last month, the Surgeon General has been authorized to hold category III nurses until a voluntary recall quota of 1,000 nurses can be effected or until the dates indicated. General Kirk stressed that the welfare of the patient comes first. He feels sure that enough former army nurses will return to duty to meet strict requirements of army medicine. Through

September 27 there have been 48,350 nurses separated. At the height of the war the Army Nurse Corps totaled 57,000 nurses.

Experienced World War II army nurses who wish to return to active duty are urged to write immediately to the Adjutant General, Washington, D. C., for application forms. They should be less than 34 years of age, physically qualified for general duty, have no dependents under 14 years of age, be unmarried and have an efficiency rating for previous service of 35 or better. They may return for two years or an unlimited period of time. Nurses may wear civilian clothes when not on duty, uniforms they wore to separation centers are authorized, and their return to duty will not prejudice their opportunities for integration into the planned Regular Army Nurse Corps.

STATISTICAL HEALTH SURVEY OF WACS IN THE WAR

The Medical Statistics Section of the Surgeon General's Office has released figures which indicate that the members of the Woman's Army Corps withstood the physical and mental ordeals of war almost as well as male soldiers. The Wacs did not show any common disqualifying weakness as a group. This conclusion is based on the hospitalization records of the 140,000 women who served in the Wacs. While the statistics are confined to nonbattle cases, they include accidental injuries and illnesses due to training or exposure.

The hospital admission rates for diseases during the last year of the war in the United States averaged 506 per thousand persons annually for all military personnel, while those for the Wacs was 793 per thousand annually.

The popular impression that women have more frequent illnesses than men under the same conditions is supported to some extent by these statistics. The common respiratory diseases and influenza comprised the greatest single cause for hospitalization in this country. In this category the statistics show that the women had a rate of 160 per thousand annually as compared with 100 for the army as a whole. The hospitalization record of Wac soldiers for nervous and mental ailments was 37 per thousand annually as compared with 40 per thousand for all troops in this country.

In the European, Mediterranean and Western Pacific theaters where there were large detachments of Wacs the data indicated that, relative to strength and the conditions to which they were exposed, a greater proportion of hospital beds were needed than for the army as a whole. In the Western Pacific between June 1944 and December 1945 a constant 3.7 per cent of the Wacs were hospitalized, as compared with 3.2 per cent of all troops, for disease and nonbattle injury only. In the Mediterranean Theater for about the same period the Wacs hospitalization rate was 3.2 as compared with 3.1 for the army as a whole. Only in the European Theater was the percentage of Wac strength hospitalized less than that for all troops: 2.2, compared with 2.5 per cent. The fact that such illnesses as trench foot and combat fatigue were due to conditions to which the women were seldom exposed would tend to decrease the differential sick rate in favor of the WAC.

MEDICAL DEPARTMENT TECHNICIANS

The number of medical department technicians trained from July 1939 to June 1946 was 114,997. During this period courses for technicians in medicine, surgery, dentistry, laboratory, pharmacy, meat and dairy inspection, medical equipment maintenance, orthopedic machinery, veterinary medicine, sanitation and x-ray were conducted at twelve general hospitals and army medical centers. Since the close of hostilities the number of training centers has been reduced to three enlisted technician schools at Brooke Army Medical Center, Fort Sam Houston, Texas; Fitzsimons General Hospital, Denver, and Wakeman General Hospital, Camp Atterbury, Indiana. The training program now has 5,200 enrolled in the three schools. After the war large numbers of technicians were released to private life, many of whom are now employed in a civilian capacity at the same jobs that they learned in the Army. Civilian hospital laboratories and clinics also employ many ex-soldiers who were trained through schooling and practical experience in a global war which saw fifteen million patients admitted to army hospitals for treatment of practically every ill known to mankind.

WITH THE 8TH ARMY IN OSAKA

The 13th U. S. Army General Hospital in Osaka, Japan, was host October 8 to the third medical conference to be held in Japan. Medical officers throughout Japan attended, including a large group of British Occupation Forces medical officers. Lieut. Col. Michael L. Sheppeck, commanding officer of the 13th General Hospital, gave the opening address, after which all the delegates were introduced. Lieut. Robert K. Curtiss of the 13th General Hospital gave the first paper, on "Primary Pleurisy with Effusion." Lieut. William H. Wilson, chief of the communicable disease section of the hospital, discussed "The Incidence of Tuberculosis in Japan." The afternoon program was given over to discussions from the floor and the presentation of cases.

FIRST PUBLIC USE OF ETHER ANESTHESIA COMMEMORATED

An exhibit of books, prints and manuscripts on the development of anesthesia opened in the Library of Congress, October 16, to commemorate with the Army Medical Library the one hundredth anniversary of the first public demonstration of ether anesthesia. The exhibit will remain on view until November 30. The discovery of surgical anesthesia was purely an American one. The exhibit illustrates the growth of man's knowledge of anesthesia from preanesthetic days until modern times.

BRUNS GENERAL HOSPITAL TO CLOSE

Bruns General Hospital in Santa Fe, N. M., is scheduled for closing on December 31, the War Department has announced. There were twenty-two army general hospitals and Old Farms Convalescent Hospital, Avon, Conn., in operation as of September 27. At the height of the war there were sixty-five army general hospitals.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel Fratis L. Duff

The Legion of Merit was recently awarded to Lieut. Col. Fratis L. Duff, M. C., A. U. S., for outstanding work from April 1944 to April 1946, during which period he served as director of training, chief, department of tropical medicine, and assistant commandant, Army Air School of Aviation Medicine. He was responsible for many advancements in the administration of the school and contributed greatly to medical research. Colonel Duff, who is now serving as assistant commandant of the School of Aviation Medicine, graduated from the University of Oklahoma School of Medicine in 1939 and entered the service July 1, 1940.

Captain Edward B. Tyson

The Bronze Star was recently awarded to Capt. Edward B. Tyson, M. C., A. U. S., of Ocean City, N. J., for meritorious achievement in connection with military operations against the enemy on Luzon, Philippine Islands, from Jan. 9 to April 26, 1945. The citation states that "Captain Tyson, battalion surgeon, performed his duties in a superior manner. On several occasions he personally made reconnaissance to foremost positions to determine satisfactory routes of evacuation, render medical attention to men of front line positions and establish advance medical installations. As a result of his superior organizational ability, sound judgment and advance preparation for every emergency, loss of life of seriously wounded personnel was kept at a minimum. His unselfish efforts and devotion to duty reflect great credit on himself and the military service." Captain Tyson has also been awarded the Purple Heart and the Combat Medical Badge. He graduated at the University of Pennsylvania School of Medicine in 1941 and entered the service Aug. 1, 1942.

Lieutenant Colonel Elton R. Blaisdell

The Bronze Star medal was recently awarded to Lieut. Col. Elton R. Blaisdell of Portland, Maine, "for meritorious service in connection with military operations, as chief of medical service, 67th General Hospital, from Dec. 5, 1942 to May 8, 1945. Lieutenant Colonel Blaisdell," stated the citation, "was directly responsible for the organization and training of the personnel of his section and for the treatment of all medical cases admitted to the hospital. His broad professional knowledge and untiring devotion to duty reflect high credit on himself and the armed forces of the United States." Dr. Blaisdell graduated from Bowdoin Medical College in 1915 and entered the service Sept. 1, 1942.

Major Harry T. Zankel

The Commendation Ribbon was recently awarded to Major Harry T. Zankel of Brooklyn. The citation read, in part, "Your service with the Medical Department when compared with others of the same grade of similar position has been exceptional, and I wish to commend you for your outstanding contribution as chief of physical therapy and occupational therapy sections, LaGarde General Hospital, New Orleans, from July 1944 to September 1945." Dr. Zankel graduated from Long Island College of Medicine, Brooklyn, in 1925 and since his release from the service he has become chief of physical medicine and medical rehabilitation at Crile Veterans General Hospital, Cleveland.

VETERANS ADMINISTRATION

GENERAL HOSPITAL AT ATLANTA

The Veterans Administration announces that the President and the Federal Board of Hospitalization have approved the construction of a 750 bed general medical and surgical hospital at Atlanta, Ga., for treatment of veterans in that area, subject to the availability of funds, and that the plans for the construction of a 333 bed addition to the present Veterans Administration hospital in Atlanta have been canceled. The existing 317 bed general medical and surgical hospital at Atlanta will be converted to a hospital for the treatment of chronic general medical and surgical patients and will be operated as an integrated unit of the new hospital. The site has not yet been selected, although it is desirable that the general medical and surgical activities of the Veterans Administration in the city be located as close as possible to Emory University Medical School in order to insure the active cooperation of medical personnel as consultants and residents. The great distance of the present hospital from the medical school precludes this factor, but it will serve efficiently as a hospital for the care of chronic cases.

HOSPITALS IN NEW YORK

Specifications for three veterans' hospitals in New York State have been approved by the Office of the Army Chief of Engineers and by the Veterans Administration. They are to be located at historic Fort Hamilton in Brooklyn, at Albany and at Buffalo and are part of the $600,000,000 construction program involving 76 hospitals and 23 major additions undertaken for the Veterans Administration by the army engineers. Each of the three hospitals will contain 1,000 beds, of which 800 are for general medical and surgical patients and 200 for neuropsychiatric patients. All three are of fireproof construction and embody the most modern hospital criteria developed as a result of experience in the last war. All three are designed to furnish utmost in care and comfort to the veteran patients.

The Fort Hamilton hospital will be located on a beautiful stretch of ground directly across the bay from Sandy Hook. The Albany hospital will be located on a site of about 20 acres near the geographic center of the city and across New Scotland Avenue from the Albany City Hospital. In Buffalo the site is in the northeast section of the city. The back campus and the athletic field of the University of Buffalo are located directly across Bailey Avenue. The remainder of the surrounding area is a first class residential district. The main building on each site will consist of a basement and ten other complete floors. The Veterans Administration hospital program to be carried out by the army engineers is said to be the largest hospital program in history.

COMPENSATION FOR WIDOWS AND CHILDREN

The Veterans Administration has announced that the widows and about 90,000 children of husbands and fathers who died as a result of service in the second world war are receiving monthly compensation benefits. The compensation for each widow is $60 per month and $18 for one child plus $15.60 for any additional children. If both parents are dead the child's legal guardian receives $30 per month. If there are two children the guardian receives $45.60 plus $12 for each additional child.

INCREASE IN VETERAN PATIENTS

The Veterans Administration announced October 7 that there had been since V-J day a 29 per cent increase in the number of veteran patients in its hospitals and homes and in hospitals under contract. The total on September 12 was 104,612, compared with 81,081 on V-J day. The largest increase occurred among World War II veterans with non-service connected disabilities. The number of such patients rose from 10,338 to 24,437, an increase of 136 per cent.

TAKE OVER ANOTHER ARMY HOSPITAL

The Veterans Administration will take over the installation (formerly the Newton D. Baker General Hospital) at Martinsburg, W. Va., as soon as the War Department's inventory has been completed. The personnel including the physicians and nurses are now being recruited. It is believed that this hospital will be used by the Veterans Administration until new veterans' hospitals are completed in West Virginia and Pennsylvania.

PERSONALS

Dr. Horace C. Dodge, for several years superintendent of the veterans' hospital at Memphis, Tenn., was recently honored for his long service in the Veterans Administration when some 450 members of the staff and employees of the hospital presented him at an informal surprise ceremony with twenty-seven American beauty roses, one for each year of his service. Dr. Dodge will reach the retiring age in a few months and plans then to live in Asheville, N. C. He served in the medical corps of the Army overseas in World War I.

Dr. Joseph P. Cohen, Newton Center, Mass., a former lieutenant colonel in the Army Medical Corps and surgeon in chief of gynecology-obstetrics at Boston City Hospital for fifteen years, has been appointed clinical director of the Cushing Veterans Administration Hospital at Framingham, Mass. Previous to this appointment he was head of the gynecology department of the Beth Israel Hospital, Boston, clinical professor in gynecology at Tufts Medical School and instructor in obstetrics at Harvard Medical School. He is a veteran of twenty-seven months' overseas with the Army in England and with the military government in Normandy, Belgium, the Netherlands and in Augsburg, Germany, where he headed the public health section of the military government detachment. A graduate of Harvard University and Harvard Medical School, he was recently appointed honorary consulting obstetrician at the Boston City Hospital.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

ALABAMA

Changes in Health Officers.—Dr. James L. Carpenter, Huntsville, has been appointed health commissioner of Madison County.——Dr. Charles J. Roehm, formerly of Eureka, Ill., has been appointed health officer of Walton County.——Dr. Claude D. Killian, Fort Payne, has resigned as acting health officer of DeKalb County.

Radiologists Organize. — The Alabama Radiological Society was recently organized with Dr. James A. Meadows, Birmingham, president; Dr. Courtney S. Stickley, Montgomery, vice president, and Dr. John D. Peake, Mobile, secretary-treasurer. The next meeting will be held during the annual session of the Alabama State Medical Association.

CALIFORNIA

Personal.—The employees of the San Francisco City and County Department of Health recently presented Dr. Jacob C. Geiger with a scroll to mark his fifteenth anniversary as director and in recognition of his services.——Dr. Mary B. Dale, Pasadena, has been appointed epidemiologist for the Los Angeles County Health Department. Newspapers report that she is the first woman to hold such a position in the county.

Public Health Appointments.—The University of California School of Public Health announces these new appointments: Dorothy B. Nyswander, Ph.D., professor of health education; Dr. Leon Lewis, recently released from military service and formerly of Newark, N. J., and New York, professor of industrial health, and Miss Edith Lindsay, recently a member of the faculty at Mills College, assistant professor in hygiene.

Grant for Physical Therapy Training.—Increased enrolment of students in the physical therapy training course of the University of California Medical School, San Francisco, has been made possible by a grant of $6,336 from the National Foundation for Infantile Paralysis, New York. Among the teaching essentials aided, the new grant will provide 236 semester hours in anatomy, physics, pathology, physiology, nursing, pediatrics and neurology. The courses, given under the direction of Dr. Frances Baker, San Francisco, include specialized treatment of infantile paralysis patients. To date, the national foundation has provided the University of California Medical School with $14,336 to aid in the training of physical therapists at that institution.

Proposed Development of Tuberculosis Facilities.—Within the next two years the Jewish Consumptive Relief Association of Los Angeles will undertake to raise $7,215,000 for the creation of a national medical center on the site of the Los Angeles Sanatorium at Duarte. The plan to extend the present tuberculosis facilities of the sanatorium to 350 beds and the establishment of 350 additional beds for the treatment of other diseases was approved unanimously at the Victory Convention of the Jewish Consumptive Relief Association, which was held in Los Angeles in August. The plan calls for the further expansion of the program, when funds are made available, to include a thoroughly equipped research department and eventually a medical school, a school for the training of medical technicians and a nurses' training school.

GEORGIA

Grants for Research.—Members of the faculty of the University of Georgia School of Medicine, Augusta, through grants of money received from the U. S. Public Health Service, will be able to carry forward several important research projects, it was recently announced. Dr. Robert B. Greenblatt and Robert B. Dienst, Ph.D., were allocated $5,550 for study of venereal diseases other than syphilis and gonorrhea. Dr. Virgil P. W. Sydenstricker receives $12,550 for research in internal medicine. An award of $14,375 was made to Dr. Harvey M. Cleckley for research in psychiatry. A part of the program will deal with electroencephalography. Dr. Cleckley's work in that field, under the new grant, will be the first studies of that kind made at the medical school.

Benefactors to Library Honored.—Bronze plaques memorializing Dr. William J. Young, Fairfax, S. C., Dr. Flournoy Carter, Augusta, and Mrs. Julia Carter Moore will be placed in the library of the University of Georgia School of Medicine, Augusta, soon. Dr. Young left a legacy of $25,000 to the medical school library when he died in 1920. Mrs. Moore bequeathed $10,000 to the medical school library in 1926 as a memorial to her father, the late Dr. Flournoy Carter. The bequest honoring Dr. Carter was used in renovating the library, and a similar amount, given by the Rockefeller Foundation, was used to purchase new books. Most of the books now being purchased for the library are bought with the income from Dr. Young's legacy. The library now has 17,536 books and receives 240 current journals published in English, French and German. The plaques will be moved to the new library whenever a new building is added to the campus under plans now being considered.

ILLINOIS

Personal.—Dr. and Mrs. Mirza P. DuComb, Patoka, observed their fiftieth wedding anniversary August 31.——Nellie P. Watts, Ph.D., New York, has been appointed research pharmacologist at the Abbott Laboratories, North Chicago.

Chicago

Branch Meetings.—The North Side Branch of the Chicago Medical Society will be addressed November 7 at the Drake Hotel by Drs. Grayson L. Carroll, St. Louis, and Arthur Steindler, Iowa City, on "Bladder Tumors" and "Revised Concepts of Infantile Paralysis—Their Application to Management and Treatment" respectively. Subsequent meetings of the branch will be addressed by:

Dr. Stanley P. Reimann, Philadelphia, December 5, The Methyl Group and Cirrhosis of the Liver.
Dr. Virgil S. Counseller, Rochester, Minn., December 5, The Applications of Vaginal Hysterectomy.
Dr. Irving S. Wright, New York, February 6, The Use of Anticoagulant Therapy in the Treatment of Diseases of the Heart and Blood Vessels.
Dr. John B. Youmans, Chicago, April 3, Nutritional Deficiencies.

New Director of Health Service at Illinois.—Dr. Frederick C. Lendrum, assistant professor of medicine, University of Illinois College of Medicine, has been appointed director of the reorganized and expanded health service at the Professional Colleges of the University of Illinois. He succeeds Dr. Eduardo A. Hurtado, who resigned to return to private practice. The new director's staff will include Dr. Joseph H. Filip, recently released from service in the army, and Dr. Elsie H. Hartman. Functions of the health service include medical attention for on-the-job injuries of faculty and staff, examination of new students and employees, and examinations legally required in connection with sick benefits and the university's retirement system. Service facilities, now being greatly expanded after the part time arrangement in effect during the war, will be integrated with the teaching, research and treatment programs in the Professional Colleges, the hospitals and the clinics.

Speech and Hearing Program. — A new educational, research and clinical program in speech and hearing rehabilitation has been inaugurated by the University of Illinois College of Medicine. Herbert Koepp-Baker, Ph.D., recently released from the navy and formerly director of the Speech and Hearing Clinic at Pennsylvania State College, will serve as director and also as director of the new speech and rehabilitation division of the Illinois Eye and Ear Infirmary. In both the medical college and the infirmary the work will be supervised by Dr. Francis L. Lederer, head of the otolaryngology department and chief of that service in the eye and ear infirmary. Dr. Koepp-Baker's appointment, said to be the first of its kind in any major university, will immediately provide instruction and clinical experience in this highly specialized field for medical students, physicians and persons working in the closely correlated nonmedical branches of special education, psychology and social work. Both undergraduate and postgraduate instruction will be included in the educational program. On the postgraduate level ear, nose and throat specialists will be further trained in the correction of speech and hearing disabilities. In the nonmedical field professional speech therapists will be trained in the correction of defective hearing and speech. Clinical facilities at the university will be utilized in furthering an expanding research program.

Million Dollars for Cancer Research.—The Goldblatt Brothers Foundation has given $1,000,000 to establish the Nathan Goldblatt Memorial Hospital at the University of Chicago. As a clinical center the hospital will be devoted exclusively to the treatment of cancer and other neoplastic diseases. The hospital will be built on Ellis Avenue, just north of 59th Street, to connect with the surgical section of Billings Hospital of the university clinics. The Nathan Goldblatt memorial will be the only university hospital in the country with the entire staff engaged full time in cancer treatment and research The hospital also will be the focus of the University of Chicago s Committee on Cancer and its associated Committee on Normal and Neoplastic Growth which coordinate research on cancer in nine clinical and basic science departments In addition to the present research facilities significant additional resources will be added soon by the laboratories of the university's Institute of Radiobiology and Biophysics and its Institute of Nuclear Studies Both institutes already have complete staffs If conditions permit, construction of the hospital will begin next spring Preliminary plans call for a six story structure which probably will be increased to seven floors with basement and sub-basement The hospital will provide at least 50 beds in single and 2 bed rooms together with the usual service features necessary for the care of patients There will be two operating rooms an outpatient clinic offices and research laboratories for the staff diagnostic laboratories, administrative quarters reception rooms for patients and their relatives, and conference rooms for the staff and the scientists working under the Committee on Cancer and the Committee on Normal and Neoplastic Growth The Goldblatt Brothers Foundation donor of the hospital is a charitable trust established in 1936 by members of the Goldblatt family and is entirely *independent of the Goldblatt Brothers Department* Stores Nathan Goldblatt, in whose memory the gift is being made, died Nov 3, 1944

INDIANA

Physician's Memory Honored—The citizens of Rockville and Park County are collecting a fund to create a memorial to the memory of the late Dr Thomas J. Collings The money will be given to the Union Hospital, Terre Haute, to be used in the purchasing of equipment or in any other manner decided by the hospital authorities

Chester Bundy Heads Tuberculosis Control—Dr Chester M Bundy recently released from service with the U S Coast Guard, has been appointed director of the division of tuberculosis control, Indiana State Board of Health, Indianapolis He succeeds Dr Carl C Kuehn, Indianapolis, who has been granted a leave to study public health at the University of Michigan

LOUISIANA

New Professor of Pediatrics.—Dr Myron E. Wegman, assistant professor of clinical pediatrics at Cornell University Medical College, New York, and director of training and research bureau of child hygiene, New York City Department of Health has been appointed professor of pediatrics and head of the department in the Louisiana State University School of Medicine, New Orleans He succeeds the late Dr Chester A Stewart

MARYLAND

The Dohme Lectures—Dr N Hamilton Fairley, Wellcome professor of tropical medicine, University of London, will give the Dohme Lectures at the Johns Hopkins University School of Medicine, Baltimore, November 20 22 His subject will be 'Chemotherapy of Malaria"

Meetings of Academy of Medicine.—On September 9 the Silver Spring Academy of Medicine opened its 1946 1947 program with a talk by Dr Thomas N Carey, Baltimore, on 'Complications of Diabetes and Their Treatment" On October 7 the speakers were Capt Rupert H Draeger (MC), Lieut Comdr Eugene P Cronkite (MC), 'The Atom Bomb at Bikini' and Rear Admiral Thomas C Anderson (MC), 'The Naval Medical Service in the Pacific War" Other speakers will be

Dr Carlton N Price, Syracuse, N Y, November 4, Newer Concepts in Gynecology
Dr Brian B Blades St Louis, December 2, Vagotomy in the Treatment of Peptic Ulcer
Dr Charles F Geschickter, Baltimore April 7 Lesions of the Breast
Dr Roscoe R Spencer, Baltimore, May 5 Recent Research Work in Cancer
Dr Neil W Swinton Ann Arbor Mich, January 6 Carcinoma of the Colon and Rectum
Dr Winfred Overholser Boston February 3, Recent Developments in Psychiatric Diagnosis and Treatment
Dr Edward J Stieglitz Bethesda Md March 3, The Significance of Geriatrics

Health Department Activities.—Dr Nels A Nelson, assistant professor of venereal diseases at the Johns Hopkins University School of Hygiene and Public Health, Baltimore, and founder of the Massachusetts Neisserian Medical Society, has been appointed director of the bureau of venereal diseases in the Baltimore City Health Department Dr Henry F Buettner Baltimore, was recently named as acting director of the bureau of social hygiene in the city health department, *succeeding* Dr Humphrey Warren Buckler Dr Buettner, formerly full time health officer of the Western Health District, was recently released from military service Dr Charlotte Silverman, Baltimore, formerly epidemiologist, Massachusetts State Department of Public Health, has joined the city health department as assistant director to Dr Miriam E Brailey, Baltimore, in the bureau of tuberculosis Dr. Thomas B Turner, professor of bacteriology, Johns Hopkins School of Hygiene and Public Health, and Dr Allen F Voshell, professor of orthopedic surgery, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, have been appointed consultants to the Baltimore department of health

MINNESOTA

Personal—Dr Sigsbee R Seljeskog Minneapolis, has been appointed superintendent of the Elizabeth Kenny Institute, Minneapolis succeeding Dr Francis E Harrington

Studies of Brucellosis—A research grant of $10,000 a year for three years has been made available to the Department of Medicine at the University of Minnesota Medical School, Minneapolis, by the U S Public Health Service for studies on brucellosis This research project is under the direction of Dr Wesley W Spink professor of medicine. Associated with him are Drs Wendell H Hall, Hartford, Conn, and Abraham I Braude Chicago Investigations are under way in an attempt to clarify the pathogenesis of brucellosis in human beings and a clinical and experimental evaluation of therapeutic agents In addition, epidemiologic studies are being extended

Physiologic Chemistry Setup in Separate Unit—Teaching and research in physiologic chemistry in the University of Minnesota Medical School Minneapolis was recently organized as a separate department with Dr Wallace D Armstrong, Minneapolis, as head Work in this field was formerly administered as a division of the department of physiology New appointments to the staff of the department include David Glick PhD Minneapolis, associate professor, Elizabeth Frame, PhD, and Saul L Cohen PhD assistant professors Other members of the department are Cyrus P Barnum Jr, PhD., Karl Sollner, PhD, and Walter O P Lundberg, PhD, associate professors and Charles I Carr, PhD, instructor

· MISSISSIPPI

State Board Awards New Fellowships.—On September 25 the Mississippi State Medical Education Board announced the names of twelve new recipients of fellowships awarded under the state s new program of assisting students in the study of medicine

Virginia Nishapter Biloxi accepted for first year at Tulane
Glenn D Baird Water Valley, who begins second year of medicine, University of Mississippi School of Medicine University
Jerrel W Benson Oakland, accepted for third year at Johns Hopkins University School of Medicine Baltimore
Marion Virginia Green Rolling Fork, who has finished first year of medicine at University of Mississippi
Aubrey Russell Harris Shannon, who has finished first year of medicine at University of Mississippi
Martin Edward Hinman Pascagoula who has finished his premedical studies
Alexander Watt Hulett Charleston accepted for first year at Tulane
James Louis McLain Jackson, accepted for first year at Louisiana State University School of Medicine New Orleans
Mary Frances Mayfield Laurel accepted for first year at Tulane
William Gaston Spence Jackson accepted for first year at Louisiana State University School of Medicine, New Orleans
Virginia Stinsel Stacy Ruleville, accepted for first year at University of Mississippi School of Medicine
George M Wilson Monticello who begins fourth year, University of Tennessee College of Medicine, Memphis

MISSOURI

Personal—Dr Gustave J Dammin recently released from military service where he had been in charge of the laboratory division in the Office of the Surgeon General, has been appointed assistant professor of internal medicine and assistant professor of pathology, Washington University School of Medicine, St Louis He will serve as director of the Central Diagnostic Laboratories at Barnes Hospital St Louis, and will aid in the teaching of laboratory diagnosis in the department of medicine The other half of his time will be devoted to research and teaching in the department of pathology

NEBRASKA

Cornerstone Laid for Children's Hospital—On September 28 the cornerstone of the Children's Memorial Hospital was laid with appropriate ceremonies by Henry Doorly publisher of the Omaha *World Herald* More than $520 000 has been raised for the complete project, but it will be necessary to raise another $100 000 during the coming winter, it was announced The *World Herald* initiated the project with a gift of $100,000 for the construction of a children's hospital on ground leased from the University of Nebraska College of Medicine. The 100 bed hospital is to be independent of the university and not a state institution (The Journal, Jan. 8, 1944, p. 114). Dr. Charles W. Poynter, dean emeritus, University of Nebraska College of Medicine, Omaha, was given particular credit in the development of the project.

NEW JERSEY

Grants for Research.—White Laboratories, Inc., Newark, has announced that its program for extramural research for the fiscal year 1946-1947 includes new grants or renewal of previous grants for experimental and clinical studies at the Jefferson Medical College, University of Pennsylvania School of Dentistry, Boston University School of Medicine, the Margaret Hague Maternity Hospital, Jersey City, Newark Beth Israel Hospital and other medical institutions. In the current fiscal year a sum approximating $40,000 has been allocated for such studies, which include problems related to bacteriology, oral medicine and surgery, hematology, nutrition, endocrinology and veterinary medicine.

NEW YORK

Physician Honored.—A dinner was held September 1 in honor of Dr. Chalmer J. Longstreet to mark his retirement after nearly thirty years' service as health officer of Binghamton. Dr. Ralph M. Vincent, Binghamton, district state health officer, was toastmaster. Dr. Paul B. Brooks, Albany, former deputy state health commissioner and the first "sanitary supervisor" of the Binghamton district, was a guest speaker. Dr. Victor W. Bergstrom, Binghamton, president of the Broome County Medical Society, spoke and commissioner of public safety Behan presented Dr. Longstreet with a gold wrist watch.

Teaching Day.—A cancer teaching day will be held at the Nelson House, Poughkeepsie, November 6, under the auspices of the Dutchess County Medical Society, Dutchess County Tumor Clinic, Tumor Clinic Association of the State of New York, Medical Society of the State of New York and the division of cancer control of the New York State Department of Health. Among the speakers will be:

Dr. Chester O. Davison, Poughkeepsie, Five Year Cancer Survivals: The Experience of the Dutchess County Tumor Clinic.
Dr. Joseph H. Farrow, New York City, Diagnostic and Therapeutic Problems in Cancer: The Experience of the Dutchess County Tumor Clinic.
Dr. Martha E. Howe, New York City, The Public Demand for Prevention and Early Diagnosis: A Sound Response.
Dr. George N. Papanicolaou, New York City, Other Types of Cell Smear in Diagnosis of Cancer.
Dr. Maurice Fremont-Smith, Boston, The Vaginal Smear in the Early Diagnosis of Cancer of the Uterus.

New York City

Personal.—Dr. Harold M. Teel is to join the medical staff of the American University of Beirut in Lebanon, it was announced by the Near East College Association September 30. Dr. Teel, visiting professor at the university, will assist in developing the departments of obstetrics and gynecology of the new $2,500,000 Dodge Medical Center.——Dr. Otto R. Pozdena, Woodside, N. Y., has been appointed acting registrar and director of the bureau of records, New York City Department of Health.

Jewish Hospital Affiliates with College of Medicine.—A teaching affiliation has been established between the Jewish Hospital of Brooklyn and the Long Island College of Medicine, Brooklyn, to provide senior students with a wider opportunity for intensive study in fields of particular interest to them. Students will be offered the choice of elective clerkships in surgery, obstetrics, pediatrics and pathology. The facilities of the Jewish Hospital with its 660 beds will be utilized for the instruction of students who elect a one or two month clerkship. This development marks a step toward the reestablishment of a normal peacetime curriculum, since such elective studies were not possible under the accelerated wartime program. The affiliation will be mutually advantageous to both institutions in forwarding medical research. The college now renders service to the people of Brooklyn through eleven affiliated hospitals and institutions where teaching services are maintained.

Well Adult Clinic Opened.—The formal opening of the Well Adult (Cancer Prevention) Clinic of the Hospital for Joint Diseases took place October 8. Dr. Harold B. Davidson, who is in charge of the clinic and attending gynecologist at the hospital, stated in a release to the press that the objective of the clinic is purely preventive and its procedures are diagnostic. It seeks to discover early symptoms and signs suggestive of cancer. The clinic does not offer any treatment. Whatever illness or disease may be discovered as a result of the examination is brought to the attention of the patient or the patient's physician, and the patient is advised to seek early advice and treatment. This clinic differs from other clinics in several essential aspects. People do not come to the clinic for relief from symptoms or conditions that are known to them but to be examined and studied when they are apparently in good health. The physical examination is by physicians in the several specialties and by technicians who do the laboratory and x-ray work. The creation of the Well Adult (Cancer Prevention) Clinic is the first step toward the inauguration at the Hospital for Joint Diseases of a disease prevention program.

OREGON

Grants Awarded Medical School.—The University of Oregon Medical School, Portland, department of pharmacology has recently received two grants for research. The Sandoz Chemical Works, Inc., New York, has provided an unrestricted grant of $2,000 for general research and for completion of studies on oxytocic and antiepileptic drugs, to be directed by Dr. Norman A. David, professor of pharmacology and head of the department, assisted by Dr. Anton C. Kirchhof and Nilkanth M. Phatak, Ph.D. The second grant of $5,000 is to be used jointly by the departments of pharmacology and otolaryngology and has been awarded by the Research Study Club and the Pacific Coast Otolaryngological Society, Los Angeles, for the purpose of investigating the effect of hormonal substances on the growth and development of the middle ear and to study the general problem of otosclerosis. This study will be under the supervision of Dr. Guy L. Boyden, professor of otolaryngology and Dr. Ben Vidgoff, research associate in pharmacology.

PENNSYLVANIA

Clinical Pathologists Organize.—Dr. William P. Belk, Philadelphia, was elected president; Dr. Fred O. Zillessen, Easton, vice president, and Dr. Henry F. Hunt, Danville, secretary and treasurer of the Pennsylvania Association of Clinical Pathologists, which was organized at a meeting held in Philadelphia, October 9. Active membership is open to graduates of medicine who are or have been actively engaged in the practice or teaching of pathology, clinical pathology or one of its subdivisions. Residents in pathology are eligible for associate membership.

State Hospital Survey.—With the appointment of Dr. Hubley R. Owen, Philadelphia, as director, a survey of the state's hospital facilities was launched. The study, which will be carried on by the Pennsylvania Committee on Hospital Facilities, Organization and Standards, was authorized by the governor May 6 when he appointed a nine member committee to determine the state's hospital facilities and needs. Dr. Owen, formerly director of health of Philadelphia, has for the past three years been director of medical services of the Philadelphia Board of Public Education, from which position he has been granted a leave to undertake the study.

Philadelphia

Chevalier Jackson Honored.—On October 7 the Cavalcade of America on its broadcast over NBC used a script entitled "That They May Live" based on the life of Dr. Chevalier Jackson, inventor of the bronchoscope and esophagoscope.

Campaign Against Diabetes.—On September 16 the department of public health, with the assistance of its advisory committee on health education, the Philadelphia Metabolic Association and the Philadelphia Diabetic Society, inaugurated an intensive educational campaign against diabetes.

New Professor of Medicine.—Dr. Richard A. Kern, recently released from the Navy Medical Corps, has been appointed professor and head of the department of medicine at the Temple University School of Medicine, and medical director of the Temple University Hospital. Dr. Kern succeeds Dr. Charles L. Brown, who has become dean of the Hahnemann Medical College (The Journal, August 24, p. 1448).

Seminar on Industrial Medicine and Surgery.—On October 22 the American Mutual Liability Insurance Company conducted a seminar on industrial medicine and surgery at the Benjamin Franklin Hotel. Among the speakers in a session devoted to the rehabilitation and reemployment of the physically handicapped were Edward P. Chester, Washington, D. C.; Dr. Bernard J. Alpers, Philadelphia, and Dr. Andre W. Reggio, Washington, D. C. Other speakers on the program included:

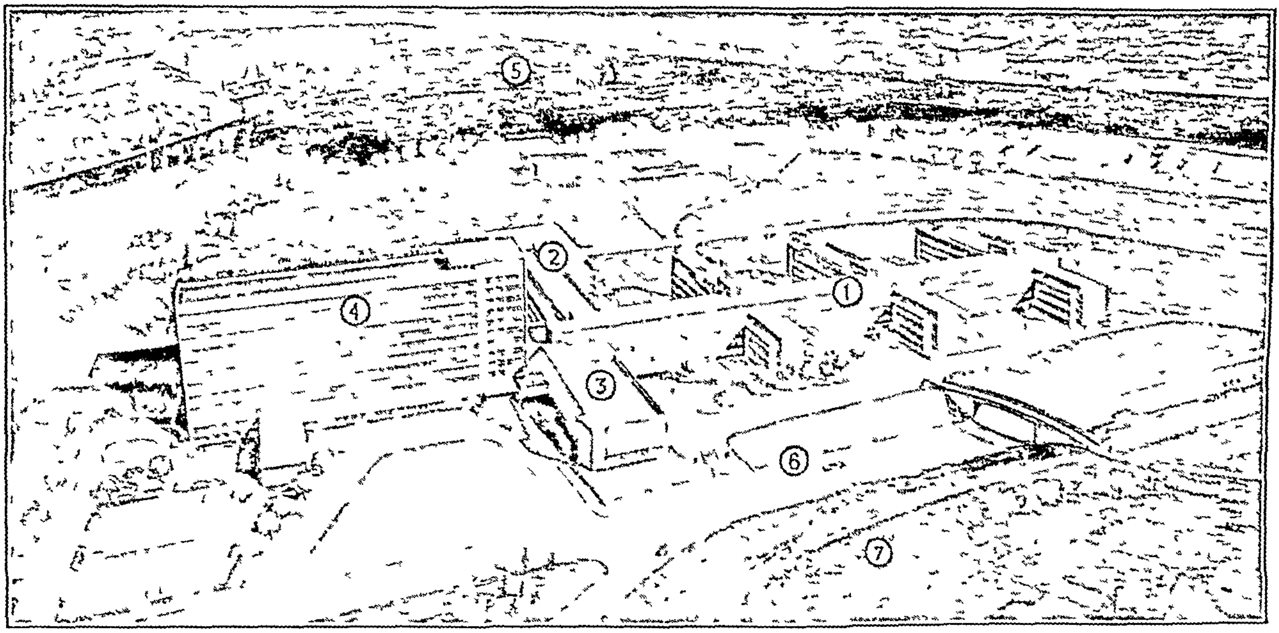
Dr. Henry C. Marble, Boston.
Dr. Connie M. Guion, New York.
Dr. Harrison L. McLaughlin, New York.
Dr. Allen F. Voshell, Baltimore.
Dr. Henry F. Ullrich, Baltimore.

WASHINGTON

New School of Medicine at Washington University.—The first class of fifty students has been admitted to the new School of Medicine at the University of Washington, Seattle. Instruction in the basic medical sciences for this class, as well as for the first class of dental students entering the new School of Dentistry at the same time, will be conducted in quarters allocated in the anatomy, chemistry, physiology and biology buildings on the University of Washington campus during the construction of new buildings for the division of health sciences. Departmental heads have been selected for all the basic medical science divisions, and the departments concerned with the immediate teaching program are well organized and adequately equipped to undertake excellent teaching and investigative activities. Appointments to date include the following personnel:

Anatomy
William F. Windle, Ph.D., professor and executive officer
Dr. John I. Worcester, professor
Dr. Howard B. Kellogg, associate professor
Dr. Frederick I. Schever, lecturer
Roland I. Becker, Ph.D., assistant professor
William W. Chambers, Ph.D., assistant professor
Dr. Robert J. Johnson, instructor
Dr. Newton B. Everett, instructor

Biochemistry
Earl R. Norris, Ph.D., professor and executive officer
Carl A. Kuether, Ph.D., assistant professor
James Mathies, M.S., associate



Projected medical, dental and nursing school for division of health sciences, University of Washington, Seattle: (1) Basic Medical Sciences, (2) Dental School laboratories and clinics, (3) library and auditorium, (4) university teaching hospital, (5) yacht basin, (6) Pacific Avenue, (7) main University of Washington campus.

Physiology
Theodore C. Ruch, professor and executive officer
Arthur W. Martin, Ph.D., associate professor
Julia G. Shahen, Ph.D., assistant professor
Loren D. Carlson, Ph.D., assistant professor.

Microbiology
Dr. Charles A. Evans, professor and executive officer
Bernard S. Henry, Ph.D., professor
Rachel L. Hoffstadt, D.Sc., professor
Russell S. Weiser, Ph.D., associate professor
Erling J. Ordal, Ph.D., associate professor
Howard C. Douglas, Ph.D., assistant professor.
Esther Duchow, B.S., associate

Pathology
Dr. Stuart W. Lippincott, professor and executive officer
Lester D. Ellerbrook, Ph.D., assistant professor
Dr. Walter A. Ricker, assistant professor

Pharmacology
Dr. James M. Dille, professor and executive officer
Dr. Daniel M. Green, associate professor

Librarian
Alderson Fry, B.L.Sc.

Plans for the medical and dental school buildings have progressed to the stage of advanced working drawings. The Board of Health Sciences and the University of Washington regents have approved the plans for the new medical center which will be located on the south end of the university campus between the Yacht Basin and Pacific Avenue. Basic medical sciences will be housed in a three story structure at the west end of the development. Library and auditorium facilities, laboratories and clinics for the school of dentistry are to be located immediately adjacent to the east, with the projected 400 bed University Teaching Hospital at the extreme east end. Maximum physical and functional integration has been considered in the development of the plans. The location of the medical center and the available land area are such that there will be ample room for expansion of facilities in the future. In 1945 the legislature of the state of Washington set aside an initial $3,750,000 with which the building program will be started as soon as plans are completed and contracts awarded. Additional funds will be requested from the next legislature for the completion of the project, which present estimates indicate will involve a total investment of from twelve to fifteen million dollars.

PUERTO RICO

Prevalence of Poliomyelitis.—Two hundred and twenty-one positive cases of poliomyelitis were registered in Puerto Rico from January 1 to October 17, indicating that the 1946 epidemic outbreak that struck the island has been the most severe since 1942, when 117 cases were accounted for. Final official figures were released this week by the Bureau of Epidemiology of the Department of Health. In 1943 there were 31 cases registered, and again in 1944 there were 14 cases. Last year the official records show 10 cases. The great increase in cases of poliomyelitis occurred in three of the principal cities on the island, namely Ponce with 35 cases, San Juan with 30 and Rio Piedras with 28, but the coefficient is more alarming in the small towns of *Patillas* and *Gurabo*, in which 9 cases were registered for each town. Of 77 municipalities in Puerto Rico the epidemic struck 47, leaving thirty towns and cities where cases were not reported.

Public Health Units Under Construction.—The government of Puerto Rico is now constructing nine public health units with an appropriation of $630,000 voted by the insular legislature in February 1945. These units will consist of a hospital and public health unit and will take care of indigent or charity cases in Las Marias, Orocovis, Adjuntas, Aguas Buenas, Rio Grande, Villalba, Dorado, Rincon and Isabela. New equipment will have to be purchased by the municipal governments in these towns.

Expansion of School of Tropical Medicine.—Dr. Pablo Morales Otero, director of the School of Tropical Medicine, has submitted to the Planning Board a program for the construction of the hygiene department of this institution and a request of funds to be allocated by the insular legislature to enlarge the existing hospital facilities in order to double its capacity from 50 to 100 beds. Plans are also under way for the construction of another building to group all the administrative offices of the school that are now in different buildings in San Juan. It is estimated that the legislature will appropriate not less than

$400,000 during the month of February for this program. In addition to this, an act passed in 1945 allocated the sum of $240,000 for the new department of hygiene of this medical school, which will be a modern building to be added to the existing facilities of the institution. The services department building will cost $200,000 and the enlargement of the hospital an additional sum of at least $200,000, according to a statement by Dr. Morales Otero. The Civil Production Administration in Washington has approved all hospital construction facilities in Puerto Rico.

GENERAL

Examination in Surgery.—The American Board of Surgery, 225 South Fifteenth Street, Philadelphia 2, announces that its next examination in part I (written) will be held in March 1947, the exact day to be set later. All applications for this examination should be on file by December 1.

Seek Candidate for Fellowship.—The Schering Corporation of Bloomfield, N. J., has provided funds for the establishment of a fellowship in the department of pharmacology at the University of Tennessee in Memphis. Candidates are requested to submit their application and qualifications to John P. Quigley, Ph.D., at the University of Tennessee, Memphis, who will award the fellowship.

Prevention of Blindness.—The National Society for the Prevention of Blindness is holding its 1946 conference at the Hotel Pennsylvania, New York, November 25-27. Sessions will be devoted to the vision program in industry, developmental eye conditions in children, medical advances in restoring and conserving vision and meeting the need for professional personnel in sight conservation. There will be also a panel discussion on glaucoma.

British Visitors.—Dr. Jean Mackintosh, senior maternity and child welfare officer of Birmingham, England, arrived in New York on October 6 to visit maternal and child health services in New York City, Boston, Philadelphia, Baltimore, Toronto, Chicago and Minneapolis. Accompanying Dr. Mackintosh is Alderman Mrs. Nellie Hyde of the Birmingham City Council, who is concerned with the administration of maternal and child health services in the English cities.

Clair Turner Joins Infantile Paralysis Foundation.—Clair E. Turner, Dr.P.H., visiting professor of health education, University of California, and consultant to the Illinois Department of Public Health and the Kansas State Board of Health, has been appointed assistant to Mr. Basil O'Connor, president of the National Foundation for Infantile Paralysis. Dr. Turner will be engaged in strengthening relationships between the school systems and the various activities of the national foundation.

Muscle Charts Available.—Under the direction of a medical committee on the treatment and after-effects of poliomyelitis a muscle chart has been prepared. This chart is a standard type of record of muscle strengths especially desirable for use in the care of poliomyelitis patients and can be used advantageously by the physical therapy departments of hospitals and clinics. These charts are available free of charge and in quantity from the National Foundation for Infantile Paralysis, 120 Broadway, New York 5.

Society for Surgery of the Hand.—The American Society for Surgery of the Hand will meet in Chicago January 24-25 under the presidency of Dr. Sterling Bunnell, San Francisco. The society was formed in January 1946 as a direct outgrowth of the interest which developed in surgery of the hand during World War II. The original group consisted of thirty-five surgeons, all of whom are primarily interested in surgery of the hand or who have contributed to the development of this field of surgery. The organization is limited in membership, is invitational and has as its objective improvement and development of surgery of the hand. Dr. Sumner L. S. Koch, Chicago, is president-elect, Dr. Henry C. Marble, Boston, vice president, Dr. Joseph H. Boyes, Los Angeles, secretary-treasurer and Dr. Thomas W. Stevenson, Salt Lake City, historian.

Van Meter Prize.—The American Association for the Study of Goiter again offers the Van Meter Prize Award of $300 and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. The award will be made at the annual meeting of the association, which will be held in Atlanta, April 3-5, provided essays of sufficient merit are presented in competition. The competing essays may cover either clinical or research investigations, should not exceed three thousand words in length, must be presented in English, and a typewritten, double spaced copy sent to the corresponding secretary, Dr. Thomas C. Davison, 207 Doctors Building, Atlanta 3, not later than January 1. A place will be reserved on the program of the annual meeting for presentation of the prize award essay by the author if it is possible for him to attend. The essay will be published in the annual proceedings of the association. This will not prevent its further publication, however, in any journal selected by the author.

Distribution of Streptomycin.—Distribution of a limited amount of streptomycin for clinical experiments in the treatment of tuberculosis will be handled by the American Trudeau Society, medical section of the National Tuberculosis Association, it was announced October 14. In response to a request by the Civilian Production Administration and a group of pharmaceutical manufacturers, Dr. H. McLeod Riggins, New York, president of the National Tuberculosis Association, has appointed a special committee headed by Dr. Horton C. Hinshaw, Mayo Clinic, Rochester, Minn., to correlate the carefully planned clinical research studies to be carried out in hospitals and sanatoriums designated by the executive committee of the American Trudeau Society. The object of these studies will be to determine the possibilities and limitations of streptomycin in the treatment of tuberculosis and to learn if the drug is sufficiently effective to justify increased commercial production, Dr. Riggins explained. Pointing out the high cost and limited quantity of the drug, Dr. Riggins said it would be impossible at this time to supply many well qualified investigators or to assign it for individual cases, regardless of the degree of urgency. Dr. Hinshaw, who has conducted studies in streptomycin for the past twenty months, warned that it has not yet been sufficiently tested to warrant large scale production and use in the treatment of tuberculosis. He emphasized that the drug cannot be regarded as a substitute for present methods of sanatorium and surgical therapy.

CANADA

Meeting of Medical Students and Interns.—The tenth annual national conference of the Canadian Association of Medical Students and Internes will be held at the medical building of McGill University, Montreal, November 14-17. Nine Canadian medical schools will send two delegates each, and an unknown number of intern groups in Canadian hospitals will be represented. Highlights of the conference will be a complete constitutional revision, the consideration of an "affiliation" with the Canadian Medical Association, the adoption of a medical film plan in conjunction with the National Film Board, and a discussion of intern remuneration. This conference culminates a year of reorganization following the disruption brought about by the accelerated courses. During this year a six member executive committee has carried through an agreement with the Canadian Medical Association for an "affiliation" of Canadian Medical Association and the Canadian Association of Medical Students and Interns, if the latter's delegates so desired at the tenth conference. The Canadian Medical Association's decision was effected at its annual reunion at Banff in June.

Marriages

Harry James Keys, Brooklyn, to Mrs. Constancia Wellington Johnson of Jacksonville Beach, Fla., recently.

Robert Boyd Lindsay, Winston-Salem, N. C., to Miss Elizabeth Grey Peden of Canton in Asheville, July 6.

Ralph Bertram Williams Jr., Wilmington, N. C., to Miss Ellen Shannon of Springfield, Tenn., July 6.

John Jerome Coyle, Chandler, Okla., to Dr. Elizabeth Irby Tutwiler of Greensboro, Ala., August 14

George Turner Howard Jr., Knoxville, Tenn., to Miss Sue Scott Crizer at Appalachia, Va., July 20.

John William Ridenour to Miss Dorothy Louise Mazza, both of Washington, D. C., July 27.

Francis M. Haugh, Appleton, Wis., to Miss Lorraine Calhoun of Waukegan, Ill., July 31.

Thomas Harding Wolever Jr., Fulton, N. Y., to Miss Helen Romano of Syracuse recently.

James H. Kelleher, Montpelier, Vt., to Miss M. Eileen Duffy of New York, July 22.

Francis H. Stern, Philadelphia, to Miss Helen Gordon of Harrisburg, Pa., June 9.

Samuel T. Killian to Miss Renee Engel, both of Syracuse, N. Y., June 15.

Deaths

Leroy Upson Gardner ⊕ Saranac Lake, N. Y.; Yale University School of Medicine, New Haven, 1914; born in New Britain, Conn., Dec. 9, 1888; following a period of graduate study at the Boston City Hospital and the Harvard Medical School, Boston, joined the faculty at Harvard as an instructor in pathology, serving in 1916-1917; returned to Yale as assistant professor of pathology, 1917-1918; an Associate Fellow of the American Medical Association, in which he had been a charter member of the Council on Industrial Health; fellow of the American Association for the Advancement of Science; member of the American Association of Pathologists and Bacteriologists and the American Society for Experimental Pathology; member of the board of directors of the National Tuberculosis Association; member of the corresponding committee on silicosis, International Labor Office, in 1930; a first lieutenant in the medical corps of the U. S. Army in 1917; trustee, village of Saranac Lake, 1932-1933, member of the water board, 1929-1930 and member of the village planning commission; for many years visiting lecturer in medicine at the University of Rochester School of Medicine; consultant pathologist at the U. S. Veterans Bureau from 1926 to 1932; formerly pathologist and for many years director of the Trudeau Foundation; since 1927 director of the Saranac Laboratory for the Study of Tuberculosis; trustee, Trudeau Sanatorium; in 1935 was awarded the Trudeau Medal of the National Tuberculosis Association for his work on the pathology of tuberculosis, notably that dealing with the relation between tuberculosis and silicosis; in 1940, at the annual meeting of the American Association of Industrial Physicians and Surgeons, was presented with the annual William S. Knudsen award for outstanding achievement in industrial medicine because of advances in the knowledge of silicosis resulting from research directed by him; in 1940 delivered the seventh annual John W. Bell lecture; co-author of "Tuberculosis—Bacteriology, Pathology and Laboratory Diagnosis" with S. A. Petroff, 1927; received the honorary degree of master of science from Yale in 1940; died October 24, aged 57.

Robert K. Lambert ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1922; born in New York Nov. 5, 1898; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology; fellow of the American College of Surgeons and the New York Academy of Medicine; clinical professor of ophthalmology at his alma mater; served during World War I and as a major in the medical corps, Army of the United States, during World War II; chief of the eye service at the Mount Sinai Hospital, where he served an internship and residency; served as attending surgeon, in charge of the ophthalmologic service of Montefiore Hospital for Chronic Diseases and later as consulting ophthalmic surgeon; died in the Doctors Hospital October 3, aged 47, of fibrosarcoma and pulmonary embolism.

James Trent Christison, St. Paul; Long Island College Hospital, Brooklyn, 1890; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; born in Southampton, England, Oct. 2, 1865; a member of the American Medical Association, serving as a member of its House of Delegates in 1918 and from 1934 to 1938; past president of the Minnesota State Medical Association and for many years a member of the editing and publishing committee; past president of the Ramsey County Medical Society; clinical professor emeritus of pediatrics at the University of Minnesota Medical School and formerly associate professor of pediatrics at the University of Minnesota Graduate School; served on the staffs of the Miller and Children's hospitals; died at Deer River, Minn., September 14, aged 81, of coronary occlusion.

Benjamin Harrison Swint ⊕ Charleston, W. Va.; College of Physicians and Surgeons, Baltimore, 1911; born in Pickens, W. Va., Aug. 14, 1888; fellow of the American College of Surgeons; member of the West Virginia Department of Health; past president of the Kanawha Medical Society; served overseas during World War I; at one time a member of the West Virginia National Guard; affiliated with St. Francis Hospital; in 1942 received from Pope Pius XII the award of "Knight of the Holy Sepulchre" for distinguished service to the church; the award of Silver Bear was presented to him by the National Council of Boy Scouts of America for "distinguished service to boyhood"; died September 7, aged 58, of acute pulmonary edema.

Torrence Calvin Moyer ⊕ Lincoln, Neb.; University of Nebraska College of Medicine, Omaha, 1914; specialist certified by the American Board of Internal Medicine; fellow of the American College of Chest Physicians and the American College of Physicians; member of the American Trudeau Society and the American Heart Association; served as president of the Lancaster County Tuberculosis Society; served during World War I; member of the staffs of the Bryan Memorial Hospital and the Lincoln General Hospital, where he died September 8, aged 58, of coronary heart disease.

Charles Edward Bradley, Colorado Springs, Colo.; University Medical College of Kansas City, 1895; died in St. Francis Hospital September 10, aged 81, of gastric hemorrhage.

James Murray Ellzey Jr., Philadelphia; Medical College of Virginia, Richmond, 1931; member of the American Medical Association; associate surgeon, Chestnut Hill Hospital; died September 8, aged 43, of coronary occlusion.

Hal S. Frazer, St. Louis; St. Louis College of Physicians and Surgeons, 1898; died in the Alexian Brothers Hospital September 8, aged 68, of coronary occlusion and carcinoma of the liver.

James Stewart Gaumer ⊕ Fairfield, Iowa; Rush Medical College, Chicago, 1900; fellow of the American College of Physicians; veteran of the Spanish-American War; on the staff of the Jefferson County Hospital; died September 10, aged 74, of coronary occlusion.

Philip Grover Hirtenstein, New York; University and Bellevue Hospital Medical College, New York, 1903; member of the American Medical Association; died August 9, aged 72, of heart disease.

Harris Ayres Houghton, Ridgewood, N. J.; Syracuse University College of Medicine, 1901; captain in the medical corps of the U. S. Army during World War I; formerly affiliated with the Flushing (N. Y.) Hospital, Manhattan Eye, Ear, Nose and Throat Hospital, Park East and Park West hospitals, all in New York, Physicians Hospital, Plattsburg and the Kingston (N. Y.) Hospital; died in the Veterans Administration Facility in Lyons, N. J., September 2, aged 72, of ruptured abdominal aortic aneurysm.

Egbert Railey Hull, Camden Point, Mo.; University Medical College of Kansas City, 1907; member of the American Medical Association; also a druggist; died in St. Joseph September 3, aged 81, of peritonitis.

Leo Jacoby, New York; Columbia University College of Physicians and Surgeons, New York, 1900; member of the American Medical Association; affiliated with the Harlem Hospital Clinic; died September 1, aged 69, of cerebral hemorrhage.

Jerome Augustine McSweeney, New York; Fordham University School of Medicine, New York, 1911; died in Bayshore Village, N. Y., June 22, aged 57, of pulmonary tuberculosis.

Daniel Flick Remer ⊕ Mount Holly, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1910; affiliated with the Burlington County Hospital; medical examiner for the Pennsylvania Railroad; died September 6, aged 66, of coronary occlusion.

David O. Roberts, Hanover, Ohio; Eclectic Medical Institute, Cincinnati, 1880; died September 10, aged 89, of congestive heart failure.

Tazwell David Rowland, Shawnee, Okla.; Memphis (Tenn.) Hospital Medical College, 1903; member of the American Medical Association; major, medical reserve corps, U. S. Army, not on active duty; on the staff of the Shawnee City Hospital; died September 3, aged 75, of uremia.

Edmund O. Sawyer, Los Angeles; Starling Medical College, Columbus, 1880; served as county health officer; died July 15, aged 94.

Joseph Scheurich, Philo, Ill.; Barnes Medical College, St. Louis, 1898; on the visiting staff of the Mercy Hospital and the Burnham City Hospital in Champaign, where he died September 7, aged 73, of coronary heart disease.

Gust Sjolander, Midland, Mich.; Saginaw Valley Medical College, Saginaw, 1903; Chicago College of Medicine and Surgery, 1912; member of the American Medical Association; died September 6, aged 74, of coronary occlusion.

Helen E. Weithaase, Vineland, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1908; died August 6, aged 72, of carcinoma of the stomach and cerebral thrombosis.

Guillermo Wills, New York; University of Pennsylvania Department of Medicine, Philadelphia, 1908; died July 2, aged 64.

George T. Zerbe, Bon Aqua, Tenn. (licensed in Tennessee in 1910); died July 30, aged 80, of heart block.

William Simpson Zimmerman ⊕ Spartanburg, S. C.; Medical College of the State of South Carolina, Charleston, 1909; died July 18, aged 62.

The National Health Service Bill

Moving the second reading of the National Health Service bill in the House of Lords, the lord chancellor said that it represented the greatest task that ever had been placed on the shoulders of one man. The minister of health was in the position of commander-in-chief planning a campaign against a very dangerous enemy, the forces of disease and ill health. But he was prevented from becoming what might be termed "a pocket Hitler." Every regulation he made must be approved by Parliament. Our hospital service had been developed in a haphazard way. The distribution of hospital services was quite irregular: there was no system at all and overlapping occurred. Many hospitals were too small to justify independence. We could not rely any longer on charity for hospital expenses. The scheme did not involve bureaucratic control. The doctors would have full freedom and scope for their professional skill.

In the debate the bill was criticized by two leading physicians. Lord Moran, president of the Royal College of Physicians, said that with regard to the control of hospitals the medical profession would rather be under the minister than under the local authorities. The minister should put into the service a small number of experienced men who were leaders of the profession. The leisure for research which able men had hitherto enjoyed should be preserved. Committees, which were the drowsy syrup of the democratic state, ate up the spare time of specialists. There was disquiet among general practitioners as to their future. They feared that under a whole time service they would lose their liberty. He had no certain answer to the question whether a whole time service was necessarily bad for the profession and for the public.

Lord Horder said that the anxiety in the profession today lay in the realization of the tremendous centralization of power vested in the minister. He had spoken many times about his "consultation" with the profession, but that was a euphemism for the most blatant form of "ipse dixitism." He hoped that the government might be persuaded to accept amendments which might preserve the voluntary hospital system and safeguard the freedom of the individual, thus deferring indefinitely the nationalization of medicine. The bill condemned every one to a dead level of mediocrity. There was no escape except through the medium of a black market in doctors, and his mind boggled at the thought of its probable immensity. They could not be blamed for thinking of it sympathetically if they believed it was the only salvation for the patient. It was the doctors' duty to do their utmost to make this experiment succeed in the best interest of the public. But the overriding duty of the doctor was not to the state but to the patient. The bill was read a second time without a division.

Sir Walter Langdon-Brown

The death at the age of 76 of Sir Walter Langdon-Brown has removed a great teacher and brilliant writer. After a distinguished career at Cambridge he completed his medical education at St. Bartholomew's Hospital and was appointed to the staff. The application to medicine of the rapid advances in physiology made at the close of the nineteenth and in the present century dominated his teaching, and no one, either by the spoken or by the written word, did so much to reveal his importance to the profession. From the first he was deeply interested in modern endocrinology, whose birth in this country took place in 1891 on the discovery by G. R. Murray in that year of the internal secretion of the thyroid gland. Langdon-Brown was one of the first to draw attention to the similarity of the effects produced by lesions of the anterior pituitary and of the adrenal cortex some years before Cushing described pituitary basophilism. A master of the brilliant phrase, he called the pituitary gland "the leader of the endocrine orchestra," and later when the importance of the hypothalamus in relation to the pituitary became clearer he described the hypothalamus as "holding the still more important rank of conductor of that orchestra." The importance of his teaching on the applications of endocrinology was recognized by his election to the presidency of the recently constituted Section of Endocrinology of the Royal Society of Medicine, although his illness prevented him from ever occupying the chair and his presidential address had to be read for him. His subject was "The Development of Endocrinology" (The Journal, August 10, p. 1238) and his treatment of it did not show any lack of his old vigor.

He was a prolific writer. His most successful book, "Physiological Principles in Treatment," first published in 1908, went through eight editions. Other works included "The Sympathetic Nervous System in Disease" (1920) and "The Endocrines in General Medicine" (1927). He was joint editor of "The Practitioner's Encyclopedia of Medical Treatment." In these books and in lectures and articles contributed to the medical press he taught medicine as applied physiology in a most luminous manner, drawing examples widely from history and literature; for his vision was not limited to the materialism of medicine but included things of the mind. In short, his outlook was philosophical, as can be seen in the titles of some of his addresses: "Thus We Are Men," "The Pursuit of Shadows," "We Have Reason to Think," "Some Gods and Their Makers," "New Pains for Old." In his later years he was much interested in medical psychology and was attracted to the school of Adler. As president of the Medical Society of Individual Psychology he contributed to several of its publications.

New Antituberculosis Program

The former antituberculosis campaign caused the death rate to go down by 40 per cent and succeeded in preventing a notable increase of the morbidity through tuberculosis after the war, but France still has about 70,000 deaths due to this illness. The object of the new law of the 31st of October 1945 is to coordinate the working of the public and private institutions with specialized doctors and officials. The basis is the "département" (district) with its dispensaries provided with district nurses ("assistantes sociales") for the detection of unknown cases by means of systematic roentgen ray and skin testing in series. Dispensaries also practice artificial pneumothorax. An antituberculosis committee for local mutual aid and health education insures aid to the tuberculous and their families and organizes health propaganda. Each district hospital will be provided for with a "départemental" center of phthisiology with the corresponding beds. The head phthisiologist is assisted by a district nurse, who coordinates the activities of all the district nurses of the "département." The center, a group organized for diagnosis, treatment, sorting, and admission to hospitals, is also the liaison organization between dispensaries and the treatment establishments. The latter are (1) "aeriums," prophylaxis centers for exposed or predisposed children; (2) preventoriums for patients with a recent primary infection or suffering from nodular erythema or from serofibrinous pleurisy (all these patients must be free from fever and their sputums must be negative); (3) sanatoriums for treatment of curable patients; (4) sanatoriums for after-treatment and readaptation. In every sanitary district (there are fifteen for the whole country) a regional consulting doctor coordinates the antituberculosis struggle in the region. In Paris a central hospitalizing office, organized by the National Committee Against Tuberculosis, keeps an up to date complete documentation and advises the "départemental" centers of the available beds. As every tuberculous person declared as such is immediately sent to a sanatorium (without waiting for the decision regarding the responsibility of the costs), it is expected to diminish the danger of contagion. Then a corps of phthisiologists selected through a competitive examination has been formed. An important part is to be played by the law on the insurance against long diseases, which at first covers two years and may be extended to five years. This law provides the insured and their families with the covering of their expenses incurred through illness. During the time of his stay in a hospital or in a sanatorium, the insured is entitled to an allocation of half his salary or of two thirds if he has dependants. During the eventual period of readaptation and professional reclassifying (which is now realizable thanks to financial arrangements and which is even declared as compulsory) the insured will have the benefit of the payment of the medical and pharmaceutical expenses and a complement of wage allocation. After being reclassified and having resumed work, he will always benefit by the paying of his medical and pharmaceutical expenses. The law covering the new organization of the campaign against tuberculosis provides similar protection for patients not belonging to the social insurance. By means of those dispositions, which have been in force since the 1st of January 1946 and through other organizations, if is expected that morbidity and mortality from tuberculosis will be diminished.

Miscellaneous

On the invitation of an American relief organization for France, the minister for population has gone to America; he will visit New York, Washington, San Francisco, Los Angeles, Chicago, Quebec, Toronto, Ottawa and Montreal and will return via Boston and New York.

On the invitation of the Iranian government, Professor Pasteur-Valery-Radot, Dr. Legroux and Professor Lacassagne have gone to Teheran to reorganize the Iranian Pasteur Institute. Dr. Balthazar has been appointed director, and the scientific council is composed of Messrs. Trefouel, Pasteur-Valery-Radot, Lacassagne, Legroux and Georges Blanc.

COPENHAGEN

Medical Practice in the Melting Pot

Last June Dr. C. Clemmesen, chairman of the Danish Medical Association, presided over a special meeting at which between 400 and 500 doctors took part in a discussion of the future of medicine in Denmark. Among those present were Dr. J. Frandsen, chief of the Danish Public Health Service, and Mr. L. P. Borberg representing the medical insurance societies. It will be recalled that some 85 per cent of the inhabitants of Denmark receive their medical care through the agency of insurance societies which started as private undertakings and which now, owing to state subsidies, have become more or less public bodies. By defending their own interests at the expense of the doctors, these societies have incurred an unpopularity in certain medical quarters amounting to definite antagonism. The special meeting enabled many doctors to ventilate their grievances, gave Dr. Frandsen an opportunity to defend his plans for converting medical practitioners into apostles of preventive medicine and enabled Mr. Borberg to take up the cudgels on behalf of the much abused insurance societies.

THE CASE AGAINST THE SICKNESS INSURANCE SOCIETIES

From the outset these societies have been haunted by the phantom of bankruptcy with the result that they have striven to keep expenses down at the cost of both patient and doctor. Doctors are remunerated according to two different systems, the first depending on an annual capitation fee of, at any rate in one district, 18 kroner, for which he treats not only the insured person but also his wife and children. According to the second system he is paid a small sum for each consultation and visit. How small the sum is has been calculated by a doctor who kept careful records of all his cases and has found that the 17,000 kroner paid him by the insurance society would have been 29,000 kroner had his insured patients been private patients. According to another calculation, only one third of the total cost of medical aid is borne by the insurance societies, the remaining two thirds coming out of the pockets of the state and local authorities. The insurance societies are also accused of exploiting the public hospitals, in which their members are treated mainly at the cost of the community.

FREE SICKNESS BENEFITS

Every Dane, whatever his income, may be admitted to a public hospital, which, if it is situated outside the city of Copenhagen, will charge him only 4 to 7 kroner a day and which, if it is in Copenhagen, will charge him the ridiculously small sum of 1.20 kroner, although the actual cost to the hospital will be between 15 and 20 kroner a day. The insurance societies bear only a small fraction of the cost of hospital treatment of their members, who, if they are treated according to the first scheme by a doctor for an annual capitation fee, cease to trouble him as soon as he has sent them to a hospital; hence the tendency on the part of the insurance societies and some doctors to overload the hospitals with their patients. There are many other ways in which medical aid can be obtained free of charge. Any one who likes to do so can call in a public health nurse free of charge and obtain advice at a public welfare maternity institution. Any one under the age of 18 can be vaccinated against diphtheria, any one can get advice at a tuberculosis station, and any woman who wants to can obtain the advice of a doctor and midwife free of charge throughout her pregnancy. Not only the fever hospitals are open to all free of charge, but the subjects of venereal disease can obtain free treatment if they so desire.

CURATIVE OR PREVENTIVE MEDICINE

Dr. Frandsen, in his capacity of senior medical officer to the Danish Public Health Service, has had much to do with the inspiration and drafting of recent public health legislation in Denmark. He is also a believer in the general medical practitioner as the hub about which all preventive as well as curative medicine should revolve. Hence his efforts to make the general medical practitioner think in terms of health rather than disease. According to a new law enacted last summer, every child in Denmark up to the age of 7 is entitled to nine medical examinations free of charge, the first three examinations being allotted to the first year of life, and one examination for every one of the following six years. This task might well have been allotted to specialists in children's diseases, and a new special service might have been organized for this purpose without reference to the general practitioner. But Dr. Frandsen held that such sidetracking of the general practitioner would be unfortunate. Hence his inclusion in the working of the new scheme. But the reaction of the more conservative element in the ranks of the general medical practitioners was exemplified by one of them, who said in public "It is quite terrible with these children from 0 to 7 years. Are we to have them also? How on earth are we to cope with it all?" It is, however, probable that this attitude is exceptional and that most general practitioners, the younger ones in particular, are willing to shoulder new responsibilities reflecting a more liberal conception of the duties of a doctor. It is not altogether irrelevant to the matter that the Danish government is providing several million kroner for the new duties it is asking the medical profession to undertake.

Correspondence

COOPERATIVE HEALTH FEDERATION

To the Editor:—The board of directors of the newly organized Cooperative Health Federation of America, whose inauguration was featured by an editorial in THE JOURNAL, August 31, wish to set before your readers a statement of the principles and aims of the federation. We trust that you will publish this letter in full, because we feel that your editorial did not accurately report our position.

The first principle on which our federation is based is that patients have the right voluntarily to organize for the purpose of securing medical attention for themselves and their families.

Free association for any purpose not inconsistent with the public interest lies at the root of our liberties. Does the American Medical Association hold that the organization of consumers to obtain physicians' services is "inconsistent with the public interest"? We cannot believe that it does. Yet we find its constituent societies in a number of states sponsoring and supporting legislation that prohibits patients from organizing plans for medical care without the express permission of the doctors. In many states in which such laws have been enacted, medical societies have set up prepayment plans; since the societies have the power to prevent the formation of other plans, their plans are clearly monopolies. A major aim of the federation is to rectify the fundamental injustice of these laws. We have no wish to debar the doctors' plans; we wish merely to give consumers equal opportunity and thus restore in every state the liberty anciently permitted under the common law.

The second principle of our federation is that consumer organized medical care plans are an instrument for bringing the art and science of medicine more effectively to more people.

When consumers organize to provide themselves with services or goods they do so to obtain more and better services and goods. In the case of medical care, the consumer's interest must first be in quality. The members of this federation understand that comprehensive medical services of high quality require well trained physicians and competent auxiliary personnel adequate facilities and equipment, and the development of a personal relationship between a patient and his doctor. To achieve these conditions requires rational organization of the doctors and allied professional personnel. It further demands close cooperation and thorough organization between those who render and those who receive the services. Group practice, developed by physicians from the needs of their science, is, in our view, the answer for professional collaboration. It has, in fact, been successfully utilized by the majority of our members. In combination with prepayment and consumer organization, group practice has demonstrated its ability to deliver a high quality of care. There is no such thing as consumer control of medical practice. In plans sponsored by consumers, doctors are free agents, free to accept or reject the proffered compensation, free to render the kind of medical service their knowledge dictates and the profession's code of ethics demands.

In support of our statement that consumer organized plans wish to improve the effectiveness of medical care, we point to our member plans in comparison with the inadequacy of medical society sponsored plans. Only a fraction of the medical society plans have advanced beyond a minimum coverage of surgical operations. Their contracts are laden with restrictions and exclusions. The consumer sponsored groups, in contrast, all show broader scopes of service and most of them place particular emphasis on personal preventive medicine.

Our member plans provide for medical service in contradistinction to cash indemnities. They seek to develop medical centers rather than sell insurance policies. Their intent is to broaden the scope and enhance the quality of medical care at the same time as they give financial protection.

For these reasons the federation stands without equivocation for consumer organized medical care plans. It does not seek any exclusive rights for consumers but believes that the right of free association and competition will bring about progressive improvement in the distribution and quality of medical care.

Our third principle is that the public has a responsibility for assuring the availability of health and medical services for all the people without economic or other barriers.

From our work in organizing and conducting local prepayment plans we are acutely aware that there are all too many American people who cannot pay for an adequate standard of modern medical care. To provide them with such care as a matter of charity is, we conceive, consistent neither with good medicine nor with fundamental social justice. We therefore support the view that public funds should be used to provide for medical care in such a way that every one may receive equal service on an equal basis.

Because medical care is essentially a personal service and by its very nature requires an understanding of the community as well as of the individual patient, we stand for decentralization of any program of public health or health insurance. The disparity of means between states makes participation by the national government imperative, but we believe that a maximum of local administration and control are essential.

In conformity with our first two principles, we also stand for freedom for every person in the selection of his or her sources of medical care, for consumer representatives on boards and committees, and for the continued encouragement of voluntary associations of consumers. Application of these principles, we believe, effectively protects the American people against mechanical and impersonal medical services.

The Cooperative Health Federation of America believes that medical service is as proper an object for organization by patients as by doctors. We do not claim perfection for our plans, nor do we think that change in the method of paying for medical care will automatically and of itself alone immediately usher in the millennium. We have had wide practical experience in the organization of health plans and do not look for miracles. But we are intent on improving the distribution of the medical arts and sciences, and we believe that we have found one valid answer to the problem in voluntary consumer organization.

COOPERATIVE HEALTH FEDERATION OF AMERICA.
GEORGE W. JACOBSON, Secretary-Treasurer, St. Paul.

Medical Motion Pictures

FILM REVIEW

Studies in Human Fertility. Black and white, sound, 1,500 feet, showing time forty-two minutes. Produced in 1940. Professional Advisers H. L Daiell, M.D , and Eric M. Matsner, M.D. Procurable from Ortho Pharmaceutical Corporation, Linden, N. J.

This motion picture presents in an authoritative, interesting and dignified manner a summary of the basis and application of methods for the control of conception. The physiology of reproduction is first presented by means of a lecture illustrated by photomicrographs and animated drawings. The medical indications for the control of conception are outlined briefly, and the various technics of contraception are discussed and illustrated. The undesirable and dangerous methods are contrasted with the accepted technics, and this is followed by a short discussion of the pharmacology of contraceptive jellies and creams. One suggestion relates to the part dealing with the temperature at which semen should be studied. Preservation is one thing and observation is another. The film leaves unanswered the question whether the refrigerated spermatozoa regain their motility if warmed to room or to body temperature. The sequence of the material is logical. The photography and general treatment are excellent. The entire presentation is well integrated and is suitable for the instruction of medical students, practicing physicians and nurses.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dental Practice Acts: Validity of Restrictions on Advertising.—The plaintiff, a practicing dentist in the District of Columbia, filed suit for a declaratory judgment to determine his right to persist in certain practices contrary to regulations promulgated by the Board of Dental Examiners. From an adverse judgment, plaintiff appealed to the United States Court of Appeals for the District of Columbia.

The dental practice act of the District provides for the creation of a Board of Dental Examiners and authorizes it to revoke or suspend the license of any dentist found to be guilty of unprofessional conduct, which among other things is declared to be: "Advertising by any medium other than . . . a modest professional card or the display of a modest window or street sign at the licensee's office, which professional card or window or street sign shall display only the name, address, profession, office hours, telephone connections and, if his practice is so limited, his *specialty*: . . ." The board was then granted authority to make such rules and regulations as it deemed necessary to effectuate the purposes of the act, *and specifically to designate the size of cards and signs.* Accordingly, the board declared that a licensee be permitted to display only two modest signs, with information thereon *confined to that allowed by the act. Window signs and signs* flush with a building may not exceed 288 square inches in area with lettering limited to 3 inches in height. Signs which *protrude from a building may not exceed 144 square inches* in area, with lettering similarly limited to 3 inches in height.

The plaintiff, said the court, has not been accustomed to advertising in an unobtrusive manner. He estimates that more than one half of his fifty to sixty patients a day are attracted by his newspaper advertisements and building signs. He has spent from $2,500 to $6,000 a year in newspaper advertising. He has placed four signs flush with his office building, 4 by 6 feet in size, on which there is lettering 4, 5 and 8 inches in height; and a large metal sign hung at an angle. Thus there are at least twice the number of signs permitted by the regulations and each of the signs flush with the building is twelve times the *maximum size allowed. The plaintiff also displays* laboratory dental work in a small show case at the entrance of his office building.

The plaintiff first urges that he is deprived of the due process of law assured him by the fifth amendment in so far as the act forbids the advertising of prices, the advertising *of free dental examinations, the display of teeth or bridgework,* and truthful advertising in general. The Court of Appeals said that other courts have so often sustained identical legislative provisions that it is somewhat surprising that the appellant apparently seriously represents an argument in this case. The terms of the act, said the court, are clear. The words "large," "*professional services*," "*indirectly*" and "advertising" have all been considered sufficiently definite and precise as used in such legislation. The limitation on newspaper advertising *is a reasonable regulation under the terms of the act.*

The plaintiff next urges that the board has no authority to designate the number of signs that he may employ, there *being no limitation in the act as to number but only as to size.* The board insists that "size" as used in the act means "aggregate size" else the congressional provision is ineffectual. We agree, said the court, that the *regulation dealing with size is* a nullity if it permits the licensee to accomplish through multiplicious production the effect denied to a single display.

The plaintiff's *final attack is against the regulation of the board* which limits the size of the advertising signs to 144 and 288 square inches, with maximum lettering of 3 inches in height. *He complains that the regulation makes no distinctions* on the basis of the size or locality of the building, the floor on which the office is located or the nature of the obstructions to the view thereof; and that the *limitation is arbitrary*, with no elasticity or discretion provided. The regulations of *the board, said the court,* are valid so long as they are not unreasonable or arbitrary. If any doubt exists as to their invalidity, they must be upheld. The precise question is whether the limitation of a dentist's office signs to 144 and 288 square inches, with maximum lettering of 3 inches in height, is clearly an unreasonable restriction under the terms of the act. Bearing in mind that the purpose of the dental practice act is to maintain high professional standards and to eliminate "bait advertising" as a means of competition, we cannot but deem the dimensional delimitations on dental displays to be reasonable, the court concluded. The law demands simplicity and reserve; the regulations of the board merely insure that these will be maintained. The board, a body of competent practicing dentists, acting under congressional authority, has determined the rules for advertising within its profession. The district court has held the regulations promulgated under that authority to be reasonable and valid. We see no sound basis on which these determinations may be disturbed. Accordingly the judgment for the defendant was affirmed.—*Johnston v. Board of Dental Examiners, D. C., 134 F. (2d) 9 (1943).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Board in Specialties were published in THE JOURNAL, October 26, page 474.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination.* Montgomery, Jan. 21-23. Secretary, State Board of Medical Examiners, B. F. Austin, M.D., 519 Dexter Ave., Montgomery.

ARKANSAS:* Little Rock, Nov. 7-8. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, Nov. 7. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CONNECTICUT:* *Examination.* Hartford, Nov. 12-13. Sec., Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic.* Derby, Nov. 12-13. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

DELAWARE: *Examination.* Dover, Jan. 14-16. *Endorsement.* Dover, Jan. 21. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

FLORIDA:* *Examination.* Jacksonville, Nov. 26-27. Sec., Dr. Harold D. Van Schaick, 2736 S.W. 7th Ave., Miami 36.

HAWAII: *Examination.* Honolulu, Jan. 13-16. Secretary, Board of Medical Examiners, Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu.

IDAHO. *Examination.* Boise, Jan. 14. Director, Board of Medical Examiners, Mrs. Agnes Barnhart, Room 355, State House, Boise.

INDIANA: *Examination.* Indianapolis, June. Exec. Secretary, Board of Medical Registration and Examination, Miss Ruth V. Kirk, 627 K. of P. Bldg., Indianapolis.

KANSAS: Kansas City, Dec. 4-5. Secretary, Board of Medical Registration and Examination, J. F. Hassig, M.D., 905 North 7th Street, Kansas City.

KENTUCKY: *Examination.* Louisville, Dec. 16-18. Sec., State Board of Health, Dr. P. E. Blackerby, 620 S. Third St., Louisville 2.

MAINE: Portland, Nov. 12-13. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MARYLAND: *Examination.* Baltimore, Dec. 10-13. Sec., Dr. E. H. Kloman, 1215 Cathedral St., Baltimore 1. *Homeopathic.* Baltimore, Dec. 10-11. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

[illegible] *ion.* Boston, Nov. 19-22. Sec., Board of Regis- [illegible] Q. Gallupe, 413-F State House, Boston 33. [illegible] Jackson, Dec. Asst. Sec., State Board of [illegible] Jackson 113. [illegible] Omaha, June 1947. Director, Bureau of [illegible] scar F. Humble, State Capitol Building, Lincoln. [illegible] Carson City, Nov. 4. Secretary, Board of [illegible] *G. H. Ross, 215 N. Carson St., Carson City.* [illegible] *xamination.* Winston-Salem, Dec. 16-19 postponed. *Endorsement.* Raleigh, Jan. 16. Act. Sec., Mrs. L. McNeill, 226 Hillsboro St., Raleigh.

NORTH DAKOTA: Grand Forks, Jan. 7-10. Secretary, Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: *Examination.* Columbus, Dec. 3-5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

SOUTH CAROLINA: Columbia, Nov. 11-12. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

SOUTH DAKOTA:* *Examination and Reciprocity.* Vermillion, Jan. 21-22. Secretary, Board of Medical Examiners, Dr. Gilbert Cottam, State Capitol Building, Pierre.

VERMONT: *Examination.* Burlington, Jan. 31-Feb. 1. Secretary, Board of Medical Registration, Dr. F. J. Lawliss, Richford.

VIRGINIA: Richmond, Dec. 3-6. Secretary, Board of Medical Examiners, Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

WASHINGTON: *Examination.* Seattle, Jan., 1947. Secretary, Mr. Nelson Vaughn, Olympia.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: Dec. 10. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

NEW MEXICO: *Examination.* Nov. 3. Sec., Miss Marion M. Rhea, State Capitol, Santa Fe.

RHODE ISLAND: *Examination. Providence, Nov. 13. Chief, Mr. Thomas* B. Casey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Sioux Falls, Dec. 6-7. Sec., Dr. G. M. Evans, Yankton.

Diet and Man's Tolerance to Cold.—Glickman and his associates carried out experiments on 12 healthy young men over a period of one hundred and fifty days to determine the effect of supplements of the water soluble vitamins to a diet containing only borderline concentrations of these vitamins on their ability to withstand repeated exposures of eight hours' duration either to intense cold (—20 F.) with considerable protective clothing or to a cool environment (60 F.) with little protective clothing. The tolerance to cold was measured by changes in rectal and mean skin temperature and in the performance of a series of psychomotor, perceptual and intellective tests The basal diet consumed by all subjects was adequate according to current standards in all essential nutrients except ascorbic acid, thiamine, riboflavin and nicotinic acid The amounts of these vitamins were generally two thirds or less of the recommended allowances of the Food and Nutrition Board of the National Research Council. The supplementary vitamins were given by capsule. When not receiving supplementary vitamins, the subjects received placebos indistinguishable from the vitamin capsules. The results of this experiment indicate that the ability to withstand the damaging effects of repeated exposures to cooling environments and to maintain normal neuromuscular and mental efficiency cannot be appreciably enhanced by giving excessive doses of ascorbic acid, thiamine, riboflavin and nicotinic acid above the amounts required for adequate nutrition. They suggest that the requirements of some of these vitamins are considerably less than the recommended allowances of the Food and Nutrition Board of the National Research Council.

Myelography in Ruptured Cervical Intervertebral Disks.—Rupture of the cervical intervertebral disks producing pain in the neck, shoulder and arm has been found by Murphey and his associates to be a fairly common lesion. They present their experience with myelography in patients having or suspected of having this condition They consider pantopaque (ethyl iodophenylundecylate) to be the opaque medium of choice At body temperature it is one seventeenth as viscid as the iodized poppyseed oils. For this reason it is more easily injected and removed, is less prone to globulation and assumes more accurately the shape of the subarachnoid space. Any portion of it which cannot be aspirated will be absorbed The authors review observations made in the course of 62 cervical myelograms, of which 28 were positive, with 16 verified at operation. They stress that in many cases the diagnosis can be made solely on the basis of clinical findings. Plain lateral and oblique roentgenograms of the cervical spine often provide helpful confirmatory information. Positive cervical myelographic findings have proved highly accurate in this small series of surgical cases The significance of negative cervical myelographic findings has not yet been completely determined, although the evidence in this series suggests that a negative picture in the cervical region is of much more value than is a negative one in the lumbar region

Phantom Nucleus Pulposus.—Phantom nucleus pulposus results in the roentgenographic appearance of an empty space or vacuum in that portion of the intervertebral disk normally occupied by this structure. Gershon-Cohen describes this phenomenon in 3 cases of traumatic spondylitis in the lower lumbar spine and in the lumbosacral articulation. All 3 patients had a history of a severe injury causing intense low backache incapacitating the patient for several weeks In no instance was there evidence of fracture or dislocation of the vertebrae. Recurrent intermittent backaches were experienced by 2 patients, while the third apparently never was troubled again after the initial injury Except for the unusual roentgenologic aspects none of the examinations revealed anything abnormal except slight limited motion of the lumbosacral spine in 2 of the 3 patients There was no neurologic evidence of herniation, yet the history of injury and the localization of the spondylitis to the area of injury leads one to the inference that trauma had some connection with the pathologic process The severe subchondral osteosclerosis which was present in each case points strongly to injury and inflammatory reaction in and around the cartilage plates. It is conceivable that loss of nuclear substance took place through defects in these cartilage plates, but no evidence of herniation was visible in the vertebral bodies, and no patient had symptoms of posterior protrusion of the nucleus pulposus The author recommends the study of the vacuum phenomena of healthy and diseased joints as an addition to the intraspinal contrast mediums

Nitrous Oxide-Cyclopropane-Curare Anesthesia: Review of 200 Cases. D. A. Holaday.—p. 426.

Caudal Anesthesia in Obstetrics.—Brown and his associates present an analysis of the first 500 cases of continuous caudal anesthesia performed at Cook County Hospital in which tetracaine hydrochloride (pontocaine hydrochloride) was employed in various concentrations both with and without a vasoconstrictor. All of the 500 cases were vaginal deliveries. Because of limitations of time and personnel, the continuous caudal method was employed in less than one tenth of all obstetric cases that were admitted during the eighteen months. A study of the pathogenesis indicates that tetracaine-epinephrine isotonic saline solution is safe and useful for caudal anesthesia, when it is administered and controlled by competent personnel. The use of a vasoconstrictor is advocated in concentrations of 1 : 200,000 epinephrine or equivalent. One to five hours' relief is obtained from each dose, reducing the frequency of injections and minimizing the likelihood of systemic effects resulting from absorption. Caudal anesthesia gives complete relief to the mother and does not cause narcotization of the baby. The rate of cervical dilatation was not significantly altered. The anesthesia and analgesia were satisfactory in 428 cases. Of the remaining 72, 13 were definite failures resulting from inability to insert the needle into the caudal canal. In 28 cases the analgesia was incomplete because of insufficient time or inadequate dosage, but in one third of these the deficiency was remedied by technical adjustments. In 16 there were technical interruptions; obstetric conditions had caused the interruptions in 9 cases.

Aseptic Meningitis Following Sympathetic Blocks.—Adelman and Irwin report 2 cases presenting a clinical picture of acute meningitis developing within six to nine hours after paravertebral sympathetic nerve blocks. The clinical course was benign and of seventy-two hours' duration; no untoward sequelae developed. Studies of the cerebrospinal fluid failed to reveal responsible bacteria. The clinical picture, the repeatedly negative bacteriologic studies and the normal cerebrospinal sugar titers pointed to a noninfectious causative agent. The authors are convinced that the meningitis was neither of bacterial nor of virus origin but was related to the lumbar sympathetic nerve blocks. The subarachnoid space was entered during the procedure and a chemical irritant was introduced intrathecally. The immediate cause of the meningitis must be found either in the equipment or in the anesthetic solution. Since contamination of lumbar equipment could be ruled out, it appears that the anesthetic solution was the immediate cause of meningitis. The absence of signs of subarachnoid block indicates that little procaine was injected intrathecally. Thus it appears unlikely that procaine was the responsible agent. The authors think that pyrogen-containing distilled water produced a chemical irritation of the meninges and acute aseptic meningitis. These cases emphasize that paravertebral sympathetic nerve blocks are not without hazard. The anesthesiologist must exert the utmost care in performing such nerve blocks. Anesthetic solutions should be prepared with pyrogen-free distilled water or isotonic solution of sodium chloride, preferably the latter.

Erysipeloid: Successful Treatment with Penicillin: Case. L. Nicholas. —p. 57.

Latent Syphilis.—Jordon and Dolce present data obtained on 169 patients with latent syphilis observed ten years or more, 100 of whom were considered well treated and 69 poorly treated. The term "latent syphilis" as employed in this study means that there were no clinical signs and symptoms of syphilis at the time of the examination. Diagnosis was usually made because of repeatedly positive serologic reactions or the birth of a congenitally syphilitic child. The authors found that there is a decided tendency for the blood serum of persons with untreated or poorly treated latent syphilis to fluctuate over a period of years. The serologic reactions of approximately 25 per cent of untreated or poorly treated persons with latent syphilis become negative spontaneously and remain so over a period of years. In 20 to 25 per cent of untreated or poorly treated persons with latent syphilis some cardiovascular complication will develop when observations are made over a period in excess of thirteen years. There is a definite relationship between the state of the serum and the ultimate clinical outcome. Persistence of strongly positive serum predicts a poor clinical outcome, whereas a tendency to fluctuate indicates a relatively good clinical outcome. There is a decided tendency for the blood serums of persons with well treated latent syphilis to fluctuate over a period of years. Adequate antisyphilitic treatment of persons with latent syphilis results in only a 17 per cent increase in long term serologic reversals over those that occur spontaneously. Adequate antisyphilitic treatment reduces the hazard of late serious complications to a minimum. There is no relationship between the state of the blood serum in persons with well treated latent syphilis and the development of late complications. Arsenical drugs are more efficacious in preventing late complications than heavy metals. Twenty to twenty-nine injections of an arsenical is adequate therapy. This should be combined with alternating courses of a heavy metal. More than this amount does not result in reduction of complications. Forty to sixty injections, and possibly less, of a heavy metal are adequate. This should be combined with adequate arsenical therapy.

Diisopropyl Fluorophosphate in Treatment of Glaucoma.—Leopold and Comroe administered diisopropyl fluorophosphate over a period of six months to 52 patients with glaucoma in one or both eyes. The patients had a total of 78 glaucomatous eyes. Other miotic agents usually had been tried before this drug was used. Patients to be treated were hospitalized, so that intraocular tensions might be estimated with a Schiøtz tonometer. Visual acuities and visual fields were tested, and ophthalmologic examinations were made weekly or biweekly. Solutions of 0.005 per cent diisopropyl fluorophosphate in oil failed to lower intraocular tension. Subsequent clinical trial indicated that 0.05, 0.1 and 0.2 per cent concentrations in oil are suitable in simple glaucoma. When a 0.2 per cent solution was ineffective, little was gained by using stronger concentrations. In the majority of the glaucomatous eyes treated with 0.05 or 0.1 per cent oil solutions of diisopropyl fluorophosphate the intraocular tension was controlled with fewer daily instillations than when either 1 per cent pilocarpine nitrate and/or 0.25 to 0.5 per cent physostigmine salicylate in water was employed. In all glaucomatous eyes successfully treated with pilocarpine or physostigmine diisopropyl fluorophosphate was also effective and usually maintained the intraocular pressure at a lower level. No dermatitis or conjunctivitis due to repetitive use of the drug was encountered. In 36 of 78 glaucomatous eyes in which treatment with pilocarpine or physostigmine had previously failed, diisopropyl fluorophosphate maintained intraocular tension below 30 mm. of mercury. It has several untoward and undesirable ocular effects such as visual blurring, brow ache and eye ache, spasm of accommodation and pericorneal injection. A slight depressant effect on serum cholinesterase could be detected from ocular instillations of diisopropyl fluorophosphate in a few cases, but no systemic symptoms were elicited.

Improving Coronary Circulation.—In order to increase impaired coronary circulation, Beck in 1935 sutured the pectoral muscle to the left ventricle and O'Shaughnessy in 1937 grafted the great omentum on to the left ventricle. Fauteux in 1940 attempted to improve the ventricular wall circulation by ligating the vena magna cordis. Vineberg has approached this problem by transplanting the left internal mammary artery directly into the left ventricular wall. He has done this in three different ways. In the first experiment on 6 dogs the internal mammary artery was tied at its distal end between two ligatures and cut. The free end was drawn through a previously prepared tunnel in the wall of the left ventricle and fixed in this position. In the second experiment, which was carried out on 7 dogs, the internal mammary artery was not cut but freed from its bed in its central portion. A slit was made in the wall of the left ventricle and the artery slung into the wound, where it was held by a free pleural graft or by sutures. In experiment 3 the left coronary sinus and anterior descending branch of the left coronary artery was tied. The internal mammary artery was sutured into the wall of the ventricle as in the second experiment. It was found that when the internal mammary artery is transplanted into the left ventricle of the heart it develops anastomotic channels with the left coronary circulation after four months. This has been demonstrated by the free flow of injection fluid from the cannulated internal mammary artery into the branches of the left coronary artery.

Action of Penicillin on Viridans Streptococci and Synergistic Effects of Sulfonamide Drugs.—Massell and his associates observed in studies on the in vitro action of penicillin on various strains of viridans streptococci that concentrations of penicillin above the minimal concentration necessary for bacteriostasis have a bactericidal action. For any strain there is a critical concentration of penicillin beyond which further increases in concentration have no increased bactericidal activity. Strains of viridans streptococci differ not only in regard to the minimal concentration of penicillin necessary for bacteriostasis but also in regard to the rate at which they are killed in the presence of an excess of penicillin. There is need for further studies concerning the possible correlation of these two variables. Variations in the number of exposed organisms do not appreciably alter the rate of the bactericidal action of penicillin. Sulfonamide drugs seem to have the following effect on the in vitro action of penicillin: 1. The minimal effective concentration of penicillin is reduced for many strains of viridans streptococci. 2. In the presence of penicillin in amounts above the minimal effective concentration, sulfonamides do not appreciably alter the bactericidal action of the penicillin.

Chronic Phosphorus Poisoning.—Heimann reports 3 instances of phosphorus necrosis of the jaw. The first patient was a man aged 40 who had been employed for eight years in the conversion department of a phosphorus plant in which yellow phosphorus was converted into red allotrope. In the radical operation that was performed the integrity of the involucrum and periosteum was not maintained. This resulted in a permanent defect of the jaw. The occurrence of joint pains in this patient is interesting, because rheumatic pains are frequent in workers exposed to yellow phosphorus. The second patient was a man aged 25 who was employed for two years in the same working area as the first patient. His illness began with pain in the region of the left lower molar teeth. Early and conservative therapy resulted in no loss of vital bone structure. The "cystic" appearance of the bone lesions is typical of early phosphorus necrosis of the jaw. The third patient, a man aged 35, had been employed in the packaging of yellow phosphorus for thirteen years. This case shows that when the upper jaw is affected in phosphorus necrosis the disease is especially serious because of its proximity to other vital structures. Upper jaw involvement responds poorly to therapy. The measures for prevention of poisoning by phosphorus are all directed at the yellow allotrope. There is no evidence that red phosphorus is poisonous. Medical control is directed essentially to the mouth. There must be preplacement and periodic medical examinations of all employees who work in areas where yellow phosphorus is handled. No one should be permitted to be employed at these processes unless his dental condition is excellent.

Mercury Hazards in Seed Treating.—Schulte says that the processing of seeds to protect them against fungi that might cause rotting in the soil before germination involves the use of mercury compounds of an extremely toxic nature in an industry where such hazards are otherwise rare. Both mercurial poisoning and dermatitis have been caused by these compounds. Ventilation, good housekeeping, personal protective equipment and adequate sanitation properly applied are needed to protect workers from these hazards.

Effervescent Mixtures to Speed Absorption of Ingested Drugs.—Lolli and Smith describe experiments on 3 healthy persons. The rate of gastric emptying after a test meal was determined. Control determinations were made with water administered ten minutes after the test meal. Later the water was replaced on separate occasions by an equal volume of fluid containing 1.5 Gm. of tartaric acid, 2 Gm. of sodium bicarbonate or an effervescent mixture of 1.5 Gm. of tartaric acid and 2 Gm. of sodium bicarbonate. The rate of emptying was not appreciably influenced by tartaric acid but was greatly shortened by sodium bicarbonate and by an effervescent mixture of the two substances. After determining the volume and hydrogen ion concentration of the stomach contents following the administration of various types of effervescent mixtures, the authors record blood concentrations of sulfathiazole, following its ingestion with and without an effervescent mixture. Another table lists blood concentrations of salicylic acid following the ingestion of acetylsalicylic acid with and without other substances. Attempts at hastening the rate of gastric emptying seem warranted when a quick effect of a drug orally administered is required with minimum irritation of the stomach. The effect attendant on the administration of an effervescent mixture seems to be due in part to the presence of weak alkaline salts and in part to the production of carbon dioxide.

Roentgenography of Adenoids. H. L. Weitz.—p. 66.

Penetrating Wounds of Brain.—Lofstrom and his associates report 23 pneumoencephalographic studies made during the care of 256 patients with penetrating cranial wounds. The time at which the pneumoencephalograms were made varied from fourteen to ninety days after the original injury, which corresponds essentially with the date of primary débridement. Following loss of cerebral tissue an enlargement of the ipsilateral ventricle was usually observed. When serious loss of tissue occurred, the contralateral ventricle also dilated and the ventricular system shifted to the affected side. The ventricular enlargement was usually proportional to the loss of tissue. Ventricular distortions occurred with small bone defects and in the presence of a tightly closed dura or dural graft. Ventricular enlargement occurred at an early period following primary débridement. During this period the hydrodynamic effect is largely a mechanical factor compensating for the loss of cerebral tissue. The common finding of localized or generalized adhesive arachnoiditis indicates a disruption of the normal cerebrospinal fluid elimination mechanism, which is of significance. It seems likely that further progression of ventricular dilatation will occur.

Pulmonary Calcifications.—Zwerling and Palmer examined 6,199 student nurses by roentgenography and tested them with tuberculin and histoplasmin. Of this number 698 showed pulmonary calcification. Among the latter group 57 were tuberculin positive, 494 were histoplasmin positive and 109 had positive reactions to both tuberculin and histoplasmin. Of the 698 persons with definite or probable calcification only 38 (5.4 per cent) were negative to both tuberculin and histoplasmin. The level of tuberculin sensitivity was approximately the same in Kansas City, Mo., as in Philadelphia, 26.3 and 26.6 per cent respectively. Four times as many student nurses showed calcification in Kansas City as in Philadelphia, and over four times as many were sensitive to histoplasmin. This suggests an association between pulmonary calcification and sensitivity to histoplasmin in the Central Eastern states. It is likely that this sensitivity is an indication of previous infection with Histoplasma capsulatum or an immunologically related organism and that infection with this organism is not necessarily grave but is widespread in subclinical form. Since in most instances it had not been possible to distinguish between tuberculin positive and histoplasmin positive calcification it may be inferred that during the active phase of the infection the x-ray appearance of the benign form of histoplasmosis can resemble tuberculosis. Consideration of the tuberculin reaction and the recovery of the tubercle bacillus is therefore essential for the final diagnosis of pulmonary tuberculosis.

Surgery and Relapse Rate of Malaria.—Kark reports 153 cases in which 176 operations were performed. Previous attacks of malaria had occurred in some of these, while in others without such a history early postoperative attacks suggested a previous latent malaria. In all these cases no form of suppressive or prophylactic antimalarial treatment was given. There was a postoperative attack of malarial fever in 10 per cent. The conditions under which observations were made render it certain that this figure of 10 per cent is in excess of the relapses brought on by surgical operation. The investigation tends to throw doubt on the assumption that surgery commonly precipitates relapses of malarial fever. The relapse rate was practically the same whether the surgical operation had been of major or minor variety. Local analgesics containing epinephrine were followed by a higher proportion of attacks of fever than were other forms of anesthesia. Three or more attacks of malarial fever during a period of two years preceding operation appeared to confer some immunity and to reduce the incidence of postoperative relapse. A first or second attack within a period of six months preceding operation seemed to increase the liability to postoperative malaria. The findings in this group of cases were compared with those found in 147 operations on patients who had received and completed suppressive treatment before operation. The postoperative relapse rate in these cases was found to be practically the same as that in which suppressive treatment had not been administered. In the third group of 1,900 surgical battle casualties suppressive quinacrine, instituted a considerable time before the battle trauma and continued throughout the period in the hospital, virtually eliminated postoperative malaria.

Sulfathiazole and Penicillin in Typhoid.—A patient with typhoid was given doses of penicillin appropriate for a staphylococcic infection with no appreciable effect on the pyrexia or blood cultures, although toxemia was much lessened and there were no complications due to ulceration. Four patients with typhoid were treated intensively with penicillin and sulfathiazole, receiving two courses each comprising 10,000,000 units of penicillin and about 34 Gm. of sulfathiazole given in four days. Speedy disappearance of toxemia, subsidence of pyrexia and disappearance of organisms from the blood, feces and urine followed the end of the second course in 3 of the 4 cases. In the fourth case, when the second course was postponed for about a fortnight there was a relapse, which rapidly subsided when the second course was initiated. Another patient with severe typhoid was treated with the combination of penicillin and sulfonamides and the conclusion was reached that there appears to be a strong case for extending this new treatment to the typhoid carrier state.

*Mental Anorexia and So-Called Hypophysial Cachexia (Conclusions Drawn from 13 Observations). J. Decourt.—p. 249.
Myxedematous Anasarca. R. Cachera.—p. 254.

Mental Anorexia and Hypophysial Cachexia.—Decourt reports 13 cases of a syndrome consisting of amenorrhea, anorexia and rapid cachexia in girls and young women between the ages of 15 and 32 years. The loss of body weight varied from 11 to 33 Kg. In 12 of the cases recovery resulted from psychic therapy and particularly from the resulting resumption of absorption of food in the absence of any opotherapy. The incidence of Simmonds's disease, conceived as a purely organic disorder due to primary atrophy of the anterior lobe of the pituitary, is rare. A large number of cases which were reported as Simmonds's disease should be reconsidered on the concept of mental anorexia. The latter condition results primarily from a psychic disorder, although a disorder of the diencephalohypophysial function may play some part in the physiopathology of mental anorexia and may explain the inaugural character of the amenorrhea. In considering mental anorexia as a psychoendocrine disorder, its origin as well as its therapy remains psychic. Complete recovery occurs from mental reeducation associated with isolation, rest in bed and resumption of food absorption, provided this treatment is not instituted too late. The return of menstruation within three to five weeks in some of the author's cases may have been the result of psychotherapy rather than that of rebuilding by the nutritive substances. Irreparable damage may have occurred prior to late treatment in cases in which amenorrhea persisted in spite of the restoration of the nutrition balance. Atrophy of the anterior lobe of the pituitary may be not only the cause but also the sequel of denutrition.

Hydronephrosis and Glomerulonephritis.—Reubi produced unilateral hydronephrosis in 2 rabbits by ligation of the ureter. At intervals of ten and thirty days respectively a hematogenous glomerulonephritis was produced in both experimental animals by the method of Masugi (injection of duck antiserum); only extremely mild inflammatory changes were, however, produced in the glomeruli of the kidneys in which the ureters had been ligated. The flow of blood in the corpuscles of Malpighi proved sufficient. Contrary to the view of other authors, it is not to be considered as assuming an important role in this phenomenon. The pressure of the urine on the wall of the pelvis of the kidney, which consequently tends to compress the loops of the glomeruli, did not exceed 20 cm. of water. With the full value of the oncotic pressure it remained inferior to the glomerular tension, but it proved equal to the pressure of filtration and exercised itself in the contrary way. It became evident that the urinary stasis is efficient in protecting the glomeruli by opposing the filtration of a toxin which results from the antigen-antibody reaction. The existence of such a toxin and its role in the pathogenesis of nephritis seem to be supported by these experiences.

Book Notices

The Management of Fractures, Dislocations, and Sprains. By John Albert Key, B.S., M.D., Clinical Professor of Orthopedic Surgery, Washington University School of Medicine, St. Louis, Missouri, and H. Earle Conwell, M.D., F.A.C.S., Orthopaedic Surgeon to the Tennessee Coal, Iron and Railroad Company, Birmingham, Alabama. Fourth edition. Cloth. Price, $12.50. Pp. 1,322, with 1,316 illustrations. St. Louis: C. V. Mosby Company, 1946.

This volume provides sane, sound and sensible advice for the treatment of fractures, dislocations and sprains. Advice against too early massage or the use of brisement forcé in after-treatment is rightly stressed. Too little reference or description, however, is detailed of efficient mechanical use of the fracture table. This seems unfortunate because it is in this technic that the average man treating fractures fails miserably. Likewise the stand taken on the use of x-ray examination is that of an aid rather than a confirmation of diagnosis and not always to be employed with a belief that clinical observation and diagnosis of fracture remain paramount. This is doubtful teaching.

The need in a textbook of this character for the chapter on workmen's compensation laws affecting fractures is not obvious. The laws of one state differ from the laws in other states.

From the standpoint of the student it is to be regretted that there are given in the text practically no references to the literature on the subjects discussed. The chapters contributed by Drs. Fincher and Brown and the chapter on the spine aided by Dr. A. G. Davis are shining exceptions and consequently much more valuable. The newer substances used for spinal myelography are not mentioned. There is a frequent use of nouns for adjectives. Several misspelled words—especially proper names—are found. Many of the illustrations are so vague and noninformative that they might better have been omitted for space saving. Figures 496, 465 and 454 seem identical, yet are printed three times.

There are frequent solecisms and lapses into informal language, as "red hot case" on page 584. Many of the pages were smudged with ink.

The text consequently, although conforming to orthodox classifications and description of the various phases of the subjects included, is loosely verbose. It wants at least two things: first a literary editor to cut about one third of the words employed and second an art editor to pose the various lesions shown in the photographs of patients covering particularly the backgrounds and to strengthen the reproductions of the rather weak appearing halftones of roentgenograms. Also might be elided the innumerable reproductions from the catalogue of a friendly splint manufacturer. Were this done, were the volume reduced in words, its ponderousness (weight 6½ pounds) would not become such a problem to student and reader and its usefulness would be enhanced. In spite of these points this book will remain one of the most popular trustworthy ones on the subject.

Studies in Hypertony and the Prevention of Disease. By I. Harris, M.D., in co-operation with J. T. Ireland, B.Sc., A.I.C., G. V. James, M.Sc., A.I.C., Edward Cronin Lowe, M.B.E., M.B., B.S., and C. E. Vernon, M.Sc., A.I.C. Cloth. Price, $3. Pp. 114, with 9 illustrations. Baltimore: William Wood & Company, 1946.

This little book purportedly deals with the influence of calcium and cholesterol in the production of hypertension, together with observations on high and low protein diets, and the interrelation of iron, phosphorus, potassium chloride, calcium and sulfur. Included are notes on the periodic examinations of normal subjects, tests for glucose tolerance, fractional gastric analysis, the influence of fats on protein metabolism, and potassium requirements. The book is poorly written and apparently published without editorial supervision. The experimental data submitted are wofully inadequate to prove any contention, yet broad generalizations are drawn and specific statements made. Most of the experiments are with rabbits and without collateral work on man. The reader is left in a quandary as to how many of the definite conclusions regarding human dietary problems could have been made. One has the impression that the answers were already in the minds of the investigators before the experiments were undertaken. Certainly from the data submitted conclusions, even regarding rabbit physiology, could not safely be drawn. The senior author has a deep-seated grudge toward certain members of the Medical Research Council (British) and, reading between the lines, it is evident that he could not voice his opinions in the regular medical journals. Therefore he resorted to the publication of a book, printed in America, to unburden his soul. This was an expedient used by some authors a century or more ago, and many of the passages are reminiscent of the haggling and innuendoes cast before the public in those days. The introduction of the book is chiefly concerned with this controversy, and there are repetitive references to it throughout the work. The senior author is especially verbose, but not eloquent, regarding the action of the council in introducing a higher calcium content into the British bread.

Psychiatry for Social Workers. By Lawson G. Lowrey, M.D., Cloth. Price, $3.50. Pp. 337. New York: Columbia University Press, 1946.

The author has described the data of modern clinical psychiatry in a fashion designed to enable the social worker to recognize and evaluate deviations in mental functioning and to refer clients properly. Emphasis has therefore been placed on indicator symptoms, and theoretical formulations are kept to a minimum. The approach is practical and direct, the relationship of psychiatry to medicine is stressed and the author's healthy attitude is manifest in his eclectic presentation. The first chapter, on the data of psychiatry, contains many useful guides to interviewing. The chapter on clinical combinations of symptoms is of special value to the social worker, who must generally classify the productions of the client as the first step in evaluating the deviation. Among the subjects covered by other chapters are the psychoses, neuroses and psychopathic personalities. The evaluation of treatment possibilities is especially good. The material is sometimes too technical and detailed for the reader who lacks medical training. The presentation of the convulsive disorders has the fault of being oriented toward institutional epileptic patients to the neglect of noninstitutional epileptic patients, who can be helped so much by the doctor and social worker team. A disproportionately large share of this book is devoted to the psychoses at the expense of adequate discussion of the neuroses and psychosomatic problems which constitute a large part of the social worker's case load.

Electrocardiography in Practice. By Ashton Graybiel, M.D., Captain, Medical Corps, U. S. Naval Reserve, Co-ordinator of Research, U. S. Naval School of Aviation Medicine, Pensacola, Florida and Paul D. White, M.D. With the Assistance of Louise Wheeler, A. M., Executive Secretary, the Cardiac Laboratory, Massachusetts General Hospital, Boston, and Conger Williams, M.D., Assistant in Medicine, Harvard Medical School, Boston. Second edition. Cloth. Price $7. Pp. 458, with 323 illustrations. Philadelphia & London: W. B. Saunders Company, 1946.

This edition is a vast improvement over the first. It is much larger, better organized and more systematic. It is divided into five parts. The first part is devoted to principles and technic. In it has been included an excellent summary of chest leads which should help the reader to gain some insight into the recent developments. The description of the manner of interpreting electrocardiograms has been improved by bringing into this section some of the material in the appendix of the previous edition.

The second part deals with the wide variations in the contour of the normal electrocardiogram; included are many new illustrations with the three chest leads CF_2, CF_4 and CF_5, which the authors now employ. The use of the term "most normal" and "least normal" to indicate uprightness of T waves in the chest leads is regrettable; it does not necessarily follow that a taller T is more normal than a smaller upright T.

The third section deals with the arrhythmias. It is introduced by a description of the analysis of an electrocardiogram in order to arrive at a differential diagnosis. This is followed by a brief evaluation of the clinical significance of arrhythmias and an extensive table showing the electrocardiographic findings in the principal arrhythmias. As a whole the illustrations in this section are adequate. In each illustration the legend is divided into an electrocardiographic interpretation, a full presentation of the clinical findings and a comment. Exception may be taken to some of the interpretations. Thus in figure 45 the authors fail to diagnose the shifting pacemaker present. In figure 49 the diagnosis of auricular paroxysmal tachycardia with aberrant conduction is not sustained by the argument; the record may very well be a ventricular paroxysmal tachycardia. In figure 53 (and in other instances dealing with complete auriculoventricular block) it would be preferable to consider that the abnormality of the ventricular complex is due to the location of the idioventricular pacemaker below the bifurcation of the common auriculoventricular bundle rather than to attribute it to bundle branch block. One cannot agree with the definition of ventricular escape given on page 104 or with the interpretation of sinuauricular block in figure 84. It is doubtful that there is auricular standstill in leads 1 and 3 of figure 85.

The fourth section takes up the electrocardiographic contour and patterns encountered in various diseases of the heart. This part has been expanded especially to show chest lead patterns. At the end of the section various artefacts are shown. This section is introduced with a general outline which is brief and to the point. Table 3, which gives a summary of the findings in the principal disturbances of the heart, may be useful to certain types of readers who are impressed with extensive tabular data. A table also is introduced to show the electrocardiographic abnormalities encountered with drugs. This is very extensive but can be criticized in the same manner as table 3. The Q waves in leads 2 and 3 of figure 89 are not prominent. The amplitude of QRS in the chest leads of figure 91 is not large. The authors fail to describe the normal appearance of the chest leads (especially the T wave) in children, which should be useful for comparison with the abnormal appearance found in congenital and rheumatic heart disease in this age group. The section dealing with recent infarction is highly to be recommended.

The last section contains an entirely new series of electrocardiograms for practice in interpretation; they serve their function excellently with a few exceptions. In figure 264 the description and interpretation are inadequate; the premature ventricular systole in lead 3 is not mentioned nor is it distinguished from the nodal escape which causes the last beat in this lead. The first beat in leads 1 and 2 of this electrocardiogram are also premature and the second beats in these leads are nodal escapes. In figure 265 the statement "the auricular action seems somewhat depressed too as though the sinus node were not working well" is ambiguous. Figure 297 is misinterpreted; it shows frequent nodal premature systoles.

In the appendix there is an extensive development of the so-called unipolar leads and of the esophageal electrocardiogram as well as a discussion of the effects of exercise and anoxemia on the electrocardiogram. In the discussion of unipolar leads the authors fall in the trap which is so common in such discussions; they state on page 433 that "the central terminal has a potential of zero" despite the fact that at the beginning of this page they more properly point out that "the potential variation is small enough to be considered zero for this purpose." Even this last statement is subject to debate.

In the illustrations the authors use two types of time lines; in the majority the time lines are 0.1 second apart; in some, however, they are 0.04 second apart. This is not always made clear, and the uninitiated reader may be confused.

It must not be taken from these criticisms, which are few and relatively minor, that the book is inaccurate or inadequate; on the contrary, it is excellent and accurate. The criticisms have been made in the hope that the few errors that have crept in may be remedied in future revisions. This book should be extremely useful to the cardiologist and internist who has some background in the field of electrocardiography and who desires to review the circumstances in which the various arrhythmias and electrocardiographic contours are encountered. He will find especially valuable the integration with the other clinical findings which the "case report" method employed lends itself to so well. To the practicing physician the case report method with stress on the clinical observations will be quite gratifying. He may find that he is learning a great deal of clinical cardiology as well as electrocardiography. The book is recommended.

Phonocardiographie: Auscultation collective (acoustique—technique—clinique). By C. Lian, professeur agrégé à la Faculté de médicine de Paris, G. Minot, et. J.-J. Welti. Préface du professeur A. Strohl. Paper. Pp. 256, with 121 illustrations. Paris: Masson & Cie, 1941.

This monograph, which appeared five years ago, covers the work which Lian and his associates have been concerned with for the past fifteen years. It is divided into three parts. The first deals with the fundamentals of acoustics and the physiology of auscultation in a rather sketchy fashion. The second part deals with technic. The principles of phonocardiographs, in particular the one developed by this French group, is described as well as the special electrocardiograph, the electrokymograph for recording pulsatory phenomena, the cardioscope and the phonograph for recording heart sounds which they developed. The third section deals with the clinical aspects of heart sounds and murmurs and is far more complete. The normal and extra heart sounds, gallop rhythm and cardiac murmurs are extensively reviewed and related to the other events in the cardiac cycle. The final two chapters deal briefly with vascular sounds and murmurs and with recording of abdominal and respiratory sounds. The bibliography included is fairly complete. The clinical section suffers, as do many reports on recorded acoustic phenomena of the heart, because the authors do not clearly distinguish the limits of their instrumental error. The vibration frequencies attributed by them to the various sounds and murmurs may represent to a varying extent the distortions imparted to them by the recording device. Nevertheless, with this limitation, the clinician will be brought up to date on the modern views of the various acoustic phenomena he is apt to encounter, particularly those views of the French school to which Lian has contributed. This monograph does not approach in scholarliness some of the other recent reviews and monographs which have appeared on this subject; however, the cardiologist acquainted with the field will find that it will repay him to peruse it.

Problems in Solutions and Dosage: Arithmetic Review. By Stella Goostray, B.S., M.Ed., R.N., Principal, The Children's Hospital School of Nusing, Boston, Massachusetts. Paper. Price, $1.50. Pp. 99, with 8 illustrations New York: Macmillan Company, 1945.

This volume is no doubt intended as a review or refresher course in the fundamental arithmetical processes together with several chapters which deal with the calculations with which nurses are involved. The forepart of the book, which deals entirely with elementary arithmetical processes, is followed by chapters on the metric and apothecary systems, solutions and dosage. The chapters on solutions and dosage may well prove of value to one who wishes to have available type formulas for calculations on these subjects. Although not being a complete textbook of the calculations with which a nurse may be involved, as a review of the topics it covers it may prove helpful.

Professional Adjustments in Nursing for Senior Students and Graduates. By Eugenia Kennedy Spalding, R.N., M.A. Third edition. Cloth. Price, $3.50. Pp. 509, with 32 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1946.

This volume is in its third edition, and there are two pages of acknowledgments indicating the extent to which the author has been associated with all the leading agencies in the field of nursing. The book is primarily of interest to nurse educators, economists and public health workers. It covers completely such subjects as social, economic and professional outlook of the graduate nurse, choice of a specialty, the professional organizations in the nursing field, and the legal and professional relationships of nurses. Each section is supplemented with an extensive bibliography and with a series of problems. The appendix is full of valuable reference data. A good index helps to complete the volume.

Analecta Psychiatrica. By J. R. Whitwell, M.B. Cloth. Price, 16s. Pp. 160. London: H. K. Lewis & Co., Ltd., 1946.

The author has collected from a great variety of writers brief paragraphs and notes concerning psychiatric subjects. Here he groups them according to such subjects as suicide, causes of mental disorder and interesting cases. The book should be especially useful to psychiatrists who have agreed to write papers for medical societies.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

HAZARDS TO MEAT PACKING WORKERS

To the Editor:—For the past fifteen years I have taken care of the injuries sustained in a local meat packing house. During that time the great majority of the injuries were lacerations caused by knives with which the employees were working. It has not been my habit during this time to administer prophylactic doses of either tetanus or gas gangrene antitoxin. There have not been any cases of tetanus or gas gangrene developed. My experience would seem to indicate that I need not now begin to use them. However, I should like to know what the usual procedure is in large meat packing houses.

M.D., Ohio.

Answer.—Both tetanus and gas gangrene antitoxin are administered to at least some workers in abattoirs who sustain puncture wounds from hooks on which meat is suspended but not to workers who have lacerations from knives. Puncture wounds occur considerably less frequently than cuts from knives. In fifteen years' experience in one abattoir tetanus or gas gangrene infection has not been observed. Such infections are not usually regarded as occupational hazards of such workers.

Pyogenic infection and infection with Erysipelothrix rhusiopathiae—erysipeloid of Rosenbach—are the chief occupational hazards among workers in abattoirs. Of 100 cases of erysipeloid reported (Klauder, J. V.: Erysipeloid as an Occupational Disease, The Journal, Oct. 8, 1938, p. 1345) 58 were observed among employees in abattoirs and an additional 3 among butchers in retail stores. It was observed in this study that erysipeloid infections occurred in 9 cases despite the application of alcohol, tincture of iodine or mercurochrome at the site of injury immediately or soon after the infliction of injury.

The application of Erysipelothrix rhusiopathiae immune serum to injuries sustained by employees in abattoirs may prevent erysipeloid. In addition to the expense of such serum, its use may interfere with treatment of such injury in the direction of preventing pyogenic infection. The prevention of pyogenic infection is probably of greater importance than is erysipeloid, since the latter infection is invariably a self-limited disease.

Erysipelothrix rhusiopathiae is sensitive to the action of penicillin (Heilman, F. R., and Herrell, W. E.: Penicillin in the Treatment of Experimental Infections Due to Erysipelothrix Rhusiopathiae; Proc. Staff Meet., Mayo Clin. **19**.340 [June 28] 1944). Local application of penicillin may serve the purpose of preventing both pyogenic infection and erysipeloid. Sulfonamide compounds were ineffective in treating Erysipelothrix rhusiopathiae infection experimentally produced in mice (Klauder, J. V., and Rule, Anna M.: "Sulfonamide Compounds in Treatment of Erysipelothrix Rhusiopathiae Infections, *Arch. Dermat. & Syph.* **49**:27 [Jan.] 1944). It is therefore not to be expected that application of a sulfonamide compound would prevent erysipeloid.

GRAFTING OF SCALP

To the Editor:—Is it possible or advisable to graft scalp for plastic procedures? A man aged 42, who received roentgen therapy of the scalp in his youth for a scalp infection, has become entirely bald. The scalp is pitted with telangiectasis and is very unsightly. He has been advised to have a plastic operation.

M.D., Michigan.

Answer.—As a rule the substitution by grafting of hair bearing skin for non-hair bearing scalp is not a satisfactory procedure from the point of view of replacing hair. In the case mentioned in the query, however, the unsightly telangiectatic scalp could be replaced by more normal looking skin. An additional and more important point which should be considered is the possibility of malignant degeneration which may occur a number of years after roentgen therapy. The last alone is ample indication for a plastic operation.

SPASMODIC TWITCHING OF TENSOR TYMPANI

To the Editor:—What are the causes of spasm or fibrillation of the tensor tympani in the absence of any demonstrable focus of irritation in the external auditory canal?

R. J. Dickinson, M.D., Ridgway, Pa.

Answer.—Spasmodic twitching of the tensor tympani is analogous to twitching which frequently occurs in the orbicularis oculi muscle and is the result of nervous fatigue. Increased rest should be advocated, and small doses of a sedative such as phenobarbital may be tried.

NEPHROSIS

To the Editor:—What is the treatment of nephrosis in a child aged 4 years? Is there such a disease as pure nephrosis? It has been my impression that most clinicians believe that a concomitant nephritis exists in these cases. What clinical and laboratory tests are important in establishing a diagnosis and following the progress of the disease? What percentage recover completely?

M.D., New York.

Answer.—While there is probably no such disease as pure nephrosis in the adult whose nephrotic syndrome begins after adolescence, there is undoubtedly a small proportion of children with the syndrome in whom the clinical and pathologic criteria of pure nephrosis are satisfied. Even in these instances the disease is primarily glomerular in origin rather than tubular, as originally believed; but the process in the glomeruli is a degenerative one, without the earmarks of inflammation as seen in glomerulonephritis. Clinically it may be impossible to differentiate pure nephrosis from the nephrotic stage of a mild glomerulonephritis unless the child has been seen very early in the disease. From the standpoint of treatment it makes little difference. The diagnosis of pure nephrosis has been made too often in the past. At the same time it must be emphasized that the extreme rarity of the disease cannot logically be used as a reason for denying its existence.

The criteria for the diagnosis of the pure nephrotic syndrome are both positive and negative. The positive group includes massive proteinuria, hypoalbuminemia, edema and effusions into body cavities, lipemia, casts and epithelial cells, including the lipoid variety, in the urinary sediment and a chronic course. The negative criteria include the absence of a history of acute nephritis, of more than the normal number of red blood cells in concentrated specimens of urine on numerous examinations, of any impairment of renal function not attributable to extrarenal factors, of hypertension and its cardiovascular consequences. Orthostatic albuminuria and cylindruria may persist for years in a child who has recovered from nephrotic glomerulonephritis and lead to a mistaken diagnosis of chronic nephrosis. The absence of other symptoms and signs is the crucial differentiating feature.

The progress of the nephrotic syndrome or disease is best measured in terms of the degree of proteinuria and edema, of the level of the serum albumin and the general state of nutrition, and of the continued absence or gradual appearance of nephritic signs. Acute infections may lead to severe relapses, death or temporary remissions. The so-called nephrotic crisis may occur with severe abdominal pain, fever, vomiting and collapse, with or without signs of bacterial peritonitis. These attacks are usually associated with striking decrease in the amino acid level of the serum (Farr, L. E., and MacFadyen, D. H.: Hypoaminoacidemia in Children with Nephrotic Crises, *Am. J. Dis. Child.* **59**:782 [April] 1940). Confusion with surgical abdominal conditions is easy.

The prognosis in the past has not been too bright for children with nephrosis, although it has been better than in those with progressive chronic glomerulonephritis, hypertension and renal insufficiency. It is probable that the present specific chemotherapy for intercurrent infections will permit a larger percentage of nephrotic children to "outgrow" their disease. Schwartz, Kohn and Weiner (Lipid Nephrosis, *ibid.* **65**:355 [March] 1943) observed 40 cases of nephrosis as the accumulated experience of twenty years, during which time 400 children with glomerulonephritis were seen; 22 of these, or 55 per cent, died within a few years; of the remaining 18, 8 were followed for seven to twenty years, and 6 had reached ages 15 to 23. Of the latter group 4 definitely showed nephritic signs and only 1 of the 8 had a normal urinary red blood cell count. Of the 12 that came to necropsy, 50 per cent showed definite glomerulonephritis, from which the authors rightly concluded that glomerular inflammation must have been present at the very onset. These patients had died between one year and three and one-half years after their illness began. The rest, with survival periods of less than a year, showed either no significant pathologic changes in the glomeruli or some congestion. In all the necropsy cases tubular degeneration was found. In a discussion of this paper Farr reported a mortality of 44 per cent among 36 children with nephrosis observed during a period of six years. Complete recovery occurred in 10 cases, or 28 per cent. In contrast are the figures given by Schwartz, Kohn and Weiner (The Prognosis of Nephritis and Nephrosis in Childhood, *New York State J. Med.* **40**:409 [March 15] 1940) for the 400 children with acute and chronic glomerulonephritis. Of the 244 children with acute nephritis 5.3 per cent died, 84 per cent recovered completely and 12 per cent developed chronic progressive nephritis. In 115 children with a diagnosis of chronic nephritis on their first admission the mortality was 50 per cent within the first year and the total mortality was 60 per cent during the period of observation. Only 8 per cent survived a five year period, and almost all of these patients had active nephritis.

As to treatment, the primary considerations are the maintenance of adequate nutrition to replenish the wasted protein and promote normal growth, the mobilization of edema and the prevention or prompt treatment of intercurrent infections. The diet should be high in calories, vitamins and proteins but low in salt. The last requirement means the use of salt free bread, salt free butter and severe restriction of the use of milk or its products. Calcium has to be supplied directly or in the form of reconstituted sodium free milk (Mead, Johnson & Co.). Edema will usually respond to these dietary measures unless the serum albumin is very low. In such instances, in which mercurial diuresis also is unsatisfactory, the most effective measure is the intravenous injection of salt poor, concentrated human serum albumin in a dosage of 25 to 50 Gm. daily for twenty to thirty or more days, depending on the amount of edema (Thorn and others: *J. Clin. Investigation* **24:**802 [Nov.] 1945). This treatment not only acts to promote diuresis but also favors protein storage and restoration of tissue protein. In some children the ordinary sodium rich concentrated human serum albumin may be effective, but the large amount of salt injected with the protein tends to defeat the purpose of the treatment. Paracentesis of the abdomen or chest should be carried out only when mechanical embarrassment of respiration or circulation exists, since the protein in the discarded fluid is lost to the body and can be regenerated only with difficulty. During a nephrotic crisis, intravenous administration of amino acids may be life saving. Chemotherapy is of course indicated during infections or suspected infections, blood transfusion for anemia and the usual vitamin, liver and iron supplements for nutritional reasons.

TREATMENT OF STOMATITIS AND GINGIVITIS

To the Editor:—Please discuss the treatment of stomatitis and gingivitis (aphthous and ulcerative). R. J. Kent, M.D., Savannah, N. Y.

Answer.—There have been no significant recent advances in the treatment of aphthous stomatitis. In the single acute type spirit of camphor, camphorated phenol, zinc chloride, silver nitrate and other preparations have given symptomatic relief. As a rule the condition is self limited (eight to fourteen days). Vitamin B complex and smallpox vaccine have also been used, particularly in the multiple recurrent type of aphthous stomatitis. The results with smallpox vaccine have not been encouraging.

In ulcerative gingivitis (ulceromembranous gingivitis, Vincent-Plaut disease, Vincent's infection, trench mouth) treatment in the past has depended primarily on four groups of drugs: (1) oxygen liberating agents (zinc peroxide, hydrogen peroxide, sodium perborate, potassium permanganate); (2) spirocheticides (arsenicals, bismuth compounds, mercurials); (3) caustics (copper sulfate, chromic acid, trichloroacetic acid, silver nitrate) and (4) dyes (gentian violet, methylene blue, acriflavine, mercurochrome). The sulfonamides have been used.

PENTACHLORPHENOL

To the Editor:—A man was exposed to pentachlorphenol spray (used in termite control) one month ago and received severe burns on the hands and face. Since then he has developed a severe cough. Examination of the larynx reveals edema, with a thick exudate. Since this is a product with five chlorine ions attached to the phenol radical I assume that he has to all intents and purposes the same reaction as that due to chlorine gas. Is there any treatment that would alleviate his paroxysms of coughing and to hasten resolution of his laryngeal state at this late date?

Carter L. Pitcher, M.D., Portsmouth, Ohio.

Answer. — Since pentachlorphenol is readily absorbable through the skin and mucous membranes, surface exposure may be more significant than for commoner surface irritants. Systemic involvement frequently and possibly regularly accompanies extensive external damage. The nature of the injuries from pentachlorphenol and related phenates is well described by McGavack, Boyd, Piccione and Terranova (*J. Indust. Hyg. & Toxicol.* **23:**239, 1941) and Deichmann, Machle, Kitzmiller and Thomas (*J. Phar.* **76:**104, 1942). The toxemia induced reveals itself through accelerated respiration, fever, glycosuria, hyperglycemia, profound muscular weakness, cardiac and vascular damage, edema and hemorrhage. Anemia and leukopenia may appear. Central nervous system injury may be prominent, and this may be reflected in such manifestations as hyperpyrexia and glycosuria. Persistence of local lesions for six weeks is not extraordinary. In the case described in the query, if the laryngeal dysfunction occurred shortly after exposure, the cause was probably pentachlorphenol. If this condition still persists, careful inquiry should be directed to the neurologic state, the hemopoietic system and the vascular system. No specific therapy for the pathologic condition of the larynx is known. Treatment should be the usual one for respiratory tract edema and bronchitis. The detection of pentachlorphenol in the urine at this remote time seems improbable.

CAUSES OF LIPEMIA

To the Editor:—Please discuss the causes of lipemia. M.D., New York.

Answer.—The normal range of values for blood plasma fats are, in milligrams per hundred cubic centimeters, fatty acids 300 to 400, total cholesterol 110 to 300 (70 per cent esterified) and phospholipid 190 to 260. The wide normal range is undoubtedly due in part to differences in methods of analysis and partially to the nutritional state of the subject at the time of bleeding. A lipemia or hyperlipemia may be manifested by a milky appearance of the plasma, although this change does not occur in every instance. Generally an increase in any one component of the fatty fraction of the blood is accompanied with some degree of elevation of the other components, although the increase need not be proportional. There is considerable evidence indicating a relationship between carbohydrate metabolism and lipemia. Insulin lowers the blood fat of lipemic diabetic patients and simultaneous glucose administration inhibits alimentary lipemia in normal dogs.

The glands and organs most concerned in carbohydrate metabolism (liver, pancreas, thyroid, pituitary and adrenals) also influence the fat content of the blood Some writers have suggested that the conditions that tend to lower the serum proteins predispose to lipemia. It has been shown that an increase in one or more of the blood fat fractions may occur following fat ingestion, in diabetes mellitus, nephrosis, hypothyroidism, xanthomatosis and severe anemia, after hemorrhage, after volatile anesthetics, in starvation, during pregnancy, in arsenical hepatitis and associated with fatty livers in chronic alcoholism.

THROMBOPENIC PURPURA

To the Editor:— A physician aged 45 has thrombopenic purpura hemorrhagica. There is no history of previous serious illness. Bleeding from the nose, tongue, gums and lips has occurred every three to four nights for the past three weeks. The coagulation and bleeding times are normal the capillary resistance test is negative; platelets number 70,000 to 90,000. The blood picture is otherwise normal. The spleen and liver are moderately enlarged. Please discuss treatment, especially the relation of climate and altitude to this disease. The patient has lived in New York for seven years. Is an altitude of 2,200 feet harmful?

M.D., New York.

Answer.—This is not the usual picture of thrombopenic purpura. Against this diagnosis is the normal bleeding time and normal capillary fragility. Further, bleeding does not usually occur in thrombopenic purpura with a platelet count above 60,000, and the spleen is not palpable in the majority of cases

Other causes of splenomegaly and thrombopenia such as liver disease and leukemia should be excluded. Further laboratory study should include liver function tests, determination of the prothrombin time in the blood and a sternal marrow aspiration.

The treatment of this condition will depend on the cause. Climate and altitude are probably unrelated to the bleeding tendency.

CORNEAL TATTOOING

To the Editor:—The accepted procedure for tattooing the cornea is staining with 2 per cent platinum chloride followed by 2 per cent aqueous hydrazine hydrate. Is there a better method of corneal tattooing?

W. Edward McGarvey, M.D., Jackson, Mich.

Answer.—The technic described in the query gives the best permanent results if the epithelium is scraped off to Bowman's membrane before using the chemicals. It is well to outline the size of the proposed area with a large 4 to 6 mm. trephine in order to have a round "pupil."

RECURRENT MALARIA

To the Editor:—What are the effects of heat, exertion and cold on chronic malaria? Can these cause recurrent attacks of malaria?

Richard A. Wills, M.D., Niagara Falls, N. Y.

Answer.—It has been a constant experience that extremes in temperature, fatigue and particularly alcohol are responsible for precipitating a relapse in malaria. However, the recurrences of this chronic disease can appear without any relationship to known external causes.

PHARMACOLOGIC BASIS OF CARDIAC THERAPY

HARRY GOLD, M.D.
New York

I have planned to present an account of pharmacologic studies which have a more or less direct bearing on problems of cardiac therapy. I shall confine my remarks, for the most part, to explorations in this field which have been made in recent years by a group of collaborators in our laboratory and clinics.[1] These relate chiefly to investigations made directly on human subjects. The term "clinical study" doesn't rate very high in scientific circles. The belief prevails that the search for facts on drug action in man directly is of necessity inexact, subject to the impressions and prejudices of the observer and not amenable to the strict control of the animal experiment. There are, to be sure, many problems in pharmacology which are inaccessible to study directly on the human subject, but there is a vast area of pharmacologic investigation which may be developed with the human subject and which, if the experiments are suitably designed, may be counted on to yield important facts in a manner which complies with the strictest demands of scientific evidence.

Action of Digitalis in Failure.—How digitalis acts to relieve heart failure has long been a matter of controversy. No doubt exists that the failing heart is able to perform more effectively under the influence of digitalis. However, we were very long in obtaining an answer to the question whether digitalis glycosides act directly on heart muscle to increase the systolic force or whether the action is entirely indirect. A few years ago an answer to that question was supplied by means of a simple preparation of the mammalian heart muscle[2] (fig. 1). The papillary muscle of the right ventricle of the cat, a muscle about 10 mm. long and weighing about 20 mg., was set up on an isometric lever, driven at a fixed rate, and its tension recorded photographically. The muscle soon began to fail, and when its force had fallen to a very low level a digitalis glycoside was administered in a concentration prevailing after therapeutic doses in man, as low as 1 part in 75 million parts of fluid. Within several minutes the force began to rise and reach high levels, at which it remained for many hours. No other chemical material is known which produces such definite and sustained increase in the systolic force of the mammalian heart muscle. While the systolic force rose, the "tone" of the muscle remained unchanged (fig. 2). An increase in the systolic force measured by its tension, as a result of a direct action on the heart muscle, may therefore be taken as the primary mechanism by which digitalis relieves heart failure. Most of the other significant changes in the heart and circulation which occur in patients with heart failure after digitalis follow as secondary adaptations.[3]

Vagal and Extravagal Action of Digitalis.—Slowing of the ventricular rate is one of the outstanding results of digitalis action in auricular fibrillation. Two mechanisms may be seen to be at work.[4] In some instances (fig. 3) blocking the vagus by 2 mg. of atropine sulfate intravenously abolishes the slowing, while in others the atropine has little influence on the slowing. In a further study of the matter we found that in one and the same person the slowing may be vagal at one time and extravagal at another (fig. 10) and further that the deciding factor is the dose of digitalis. As the dose is increased the control of the ventricular rate tends to pass from the vagal to the extravagal mechanism. It is important to note that in the operation of this adaptive mechanism the resting rate may remain unchanged.

In another investigation[5] we observed that physical exercise to the limit of the patient's endurance has the same effect on rate as blocking the vagus with atropine (fig. 4). When slowing is by the vagal mechanism (abolished by atropine) exercise may accelerate the rate to 180 a minute, but when the slowing is by the extravagal mechanism (not abolished by atropine) exercise rarely accelerates the rate above about 100 a minute. This is a matter of some importance in the maintenance of patients with auricular fibrillation. In the treatment of these patients it is not uncommon to find digitalis reducing the rate from 140 to 70 when the patient is at rest. When he is up and about, however, he complains of palpitation and breathlessness. Free physical activity raises the rate to uncomfortable peaks when the mechanism of control is vagal. If larger doses of digitalis are given, the rate control passes to the extravagal mechanism, which prevents the exaggerated acceleration with exercise, even though the resting rate may not be materially lowered. These mechanisms are illustrated diagrammatically in figure 5.

U. S. P. Assay of Digitalis.—The potency of digitalis preparations is known to vary. The latest revision of the U. S. Pharmacopeia adopted the cat method of assay as a means of securing uniformity. In this method the unknown preparation and the Standard Reference Digitalis are injected intravenously into cats and the ratio of their lethal doses is determined. The unknown is so adjusted that 0.1 Gm. produces the effect of 0.1 Gm. or 1 U. S. P. unit of the Standard. This is by intravenous injection in cats. But digitalis preparations differ in their absorbability, and they are usually given by mouth in man. A material that is potent by vein may be weak by mouth if it is poorly absorbed.

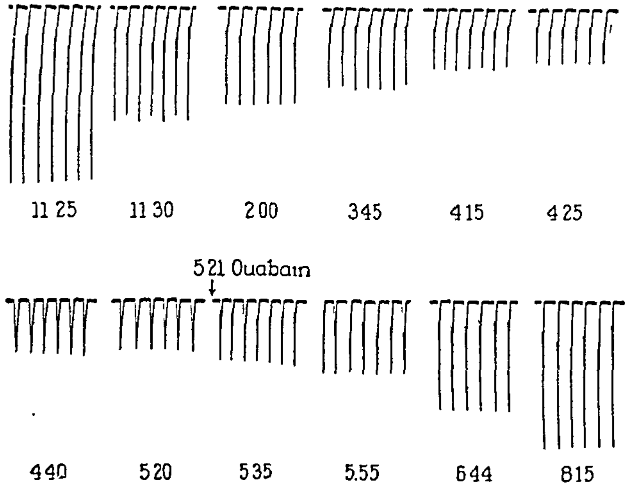

Fig. 1.—Effect of digitalis glycoside on the systolic force of mammalian heart muscle.

Human Assay of Digitalis.—To overcome this difficulty we developed a method for the assay of digitalis preparations by oral administration in man.[6] The method follows the basic principles of bioassay. A suitable sensitive individual is calibrated by the Standard Digitalis Powder of the U. S. Pharmacopeia. Figure 6 shows a case that is (Mi. La.) and one that is not (Es. As.) suitable. Calibration involves ascertaining whether the patient in question can distinguish 25 per cent differences in the doses of the Standard by changes in the T wave of the electrocardiogram. In an assay (fig. 7) a tracing is taken, a dose is given and a second tracing is taken twenty-four hours later for the effect on the T wave. A month is allowed to elapse for elimination. The pair of tracings and a dose of the Standard are repeated at monthly intervals. Each dose is about 25 per cent larger than the previous one. The Unknown is then similarly tested in doses which produce effects falling within the calibration points of the Standard. The matching of electrocardiograms is all done with the "blind test." In this way one determines how much of the Unknown produces the same effect as a given amount of the Standard. Since any 1 patient may show abnormal behavior, the test is repeated on 6 or 8 similarly calibrated patients (table 1). From the average of these, one obtains the amount of the Unknown specimen which produces in human beings, by oral administration, the same effect as 100 mg. of the Standard Reference Powder, or 1 U. S. P. unit. The results by the Human Method are reproducible with a high degree of precision as seen from the potency of preparations reassayed several times[7] (table 2).

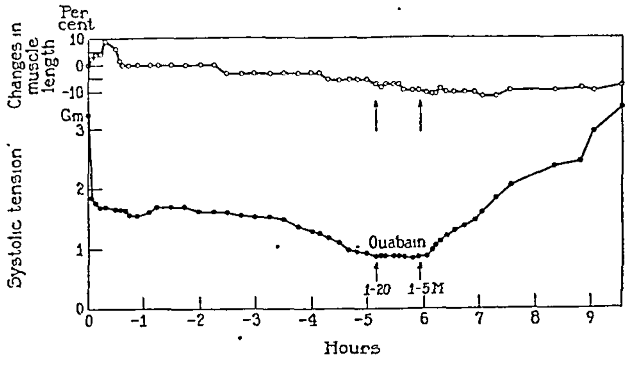

Fig. 2.—Changes in systolic and diastolic tension ("tone") of papillary muscle during action of digitalis glycoside.

How different are the answers by the two methods of assay? We have secured some idea about that from a series of preparations which were tested by the two methods. The results are shown in table 3. Imagine each of these preparations put up in a tablet of 1 U. S. P. unit as determined by the official intravenous cat method. You will note that for different specimens of digitalis labeled 1 U. S. P. unit one tablet may produce three times as much effect as another, and in the case of purified glycosides one tablet may produce about ten times as much effect as another. This matter is quite serious if it is not clearly understood, for 10 U. S. P. units of lanatoside C (Cedilanid) would be insufficient to digitalize a patient, whereas 10 U. S. P. units of digitoxin might prove fatal. The human method of assay seems to be the only present remedy to the problem of securing uniformity of digitalis preparations for oral administration in man.

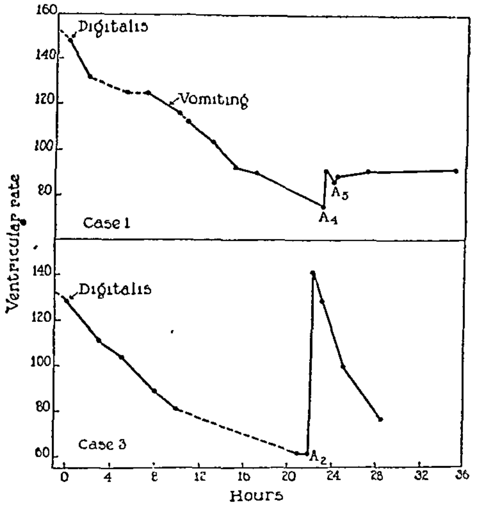

Fig. 3.—Effect of atropine sulfate after digitalis in 2 cases of heart failure with auricular fibrillation. Each patient received a large dose of digitalis and showed the usual response. Each intravenous dose of atropine sulfate (A_2, A_4, A_5) was 2 mg.

Absorption of Digitalis Glycosides.—We may now turn to the subject of the absorption of digitalis materials from the gastrointestinal tract. We approached the study of this matter by comparing the size of the oral and intravenous doses necessary to produce the same effect in patients with auricular fibrillation. This ratio of oral to intravenous dose is a practical index of absorption for the vast majority of digitalis materials. The patient is put to bed, the ventricular rate is counted several times daily during a control period, and, when the rate has stabilized, a large dose is given at one time by mouth or by vein as the case may be, and similar counts of the ventricular rate are made at frequent intervals during the day until the full effects have developed. By means of this method it was found that digitoxin is practically completely absorbed[8] (fig. 11), since a dose produces the same effect whether given by mouth or by vein. About 20 per cent of a dose of digitalis is absorbed, and only about 10 per cent of a dose of lanatoside C (fig. 8). Complete absorption from the gastrointestinal tract is a rare experience in pharmacology. There are very few drugs for which the oral and intravenous doses are the same.

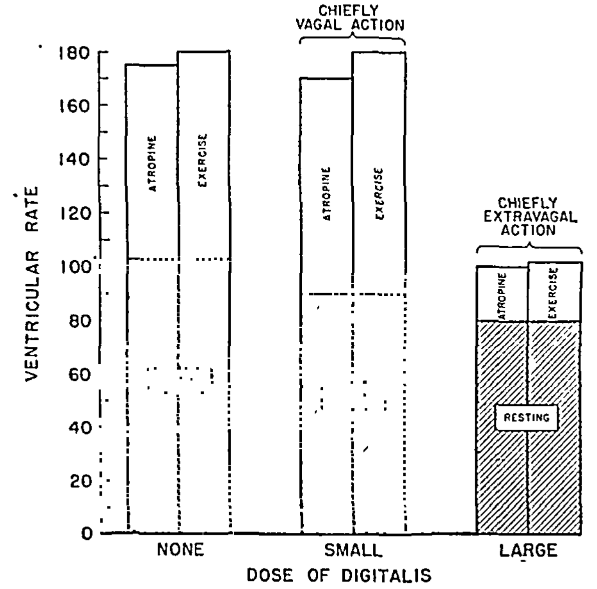

Fig. 4.—Effects of exercise and of atropine on the heart rate in 11 ambulant patients with heart failure and auricular fibrillation after small and large doses of digitalis.

Single Average Full Dose Method of Digitalization.—The human assay of digitoxin by the T wave shows that 1 mg. produces the same effect in man by oral administration as 1 Gm. of the Standard Digitalis Powder. The same relationship was found to apply to the effects in auricular fibrillation[8] (fig. 12). The fact that digitoxin is so potent and so well absorbed suggested the possibility of employing it in a single dose method of digitalization to replace the multiple dose methods employing digitalis leaf or the tincture.[9] Our results indicate that the most favorable routine technic for digitalizing patients is to administer 1.2 mg. of digitoxin at one time. This produces a high degree of digitalization in a period of about six to ten hours in the place of the twenty-four to forty-eight hour period required for the divided dose methods in which digitalis is used. One cannot use the digitalis leaf or the tincture by this method, because the equivalent amount of digitalis, namely 1.2 Gm., will cause nausea or vomiting by local action in about 10 to 20 per cent of the cases. The therapeutic effects are maintained in the majority of cases by a single daily dose of a tablet of 0.2 mg. The use of digitoxin in this way has greatly simplified the problem of digitalization.

Variations in Human Susceptibility to Digitalis.—Some difficulty has been encountered in gaining general acceptance of the idea that it is proper to use an average full digitalizing dose of digitoxin at one time in a routine manner. The argument is that patients vary too much, that the most tolerant ones will escape full digitalization and the most susceptible ones will be poisoned. It is indeed a fact that some patients need closer to 2 mg. to digitalize them fully. From our experience with more than 1,000 single dose digitalizations with 1.2 mg. a negligible number, about 2 out of 100, show nausea or vomiting. The safety of this method is therefore beyond question. In this connection I may call attention to a fact pointed out by Clark[10]

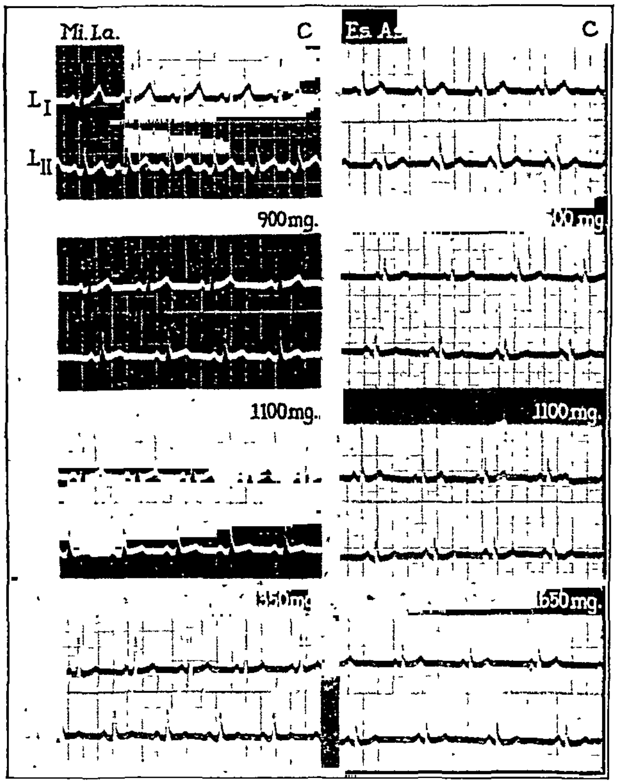

Fig. 6.—Selection of patients for human assay of digitalis. *C* is control before digitalis. Patient Es. As. is not suitable for assay because he can't distinguish 500 mg. from a dose more than three times as large by the T wave change. Patient Mi. La. is satisfactory for assay because the T waves become distinctly lower with dose increments of 25 per cent or less.

and others that digitalis action in animals is very uniform as drugs go. We recently prepared a distribution curve of digitalis action after oral administration in 86 patients (833 doses) based on the threshold doses causing a T wave change in the electrocardiogram[11] (fig. 12). The curve is very similar to that observed in the cat. Variation of patients' sensitivity from the approximate mean is not great. A dose ± 25 per cent of the mean includes about 70 per cent of the cases. Such variations in dosage are hardly detectable in clinical digitalization. A dose ± 50 per cent of the mean, which would hardly be expected to cause either serious underdigitalization or overdigitalization, includes more than 90 per cent of the cases. There is therefore a sound pharmacologic basis for the validity of the single average full dose method of digitalization. What was needed was a preparation of digitalis which could be given in that way without irritating the stomach. As I have already indicated, digitoxin meets that need because of two characteristics. It is so potent and so well absorbed that the approximate mean oral digitalizing dose involves only 1.2 mg. of glycoside, an amount too small to cause local gastrointestinal irritation, also an amount smaller than that required for any other glycoside in common use at the present time.

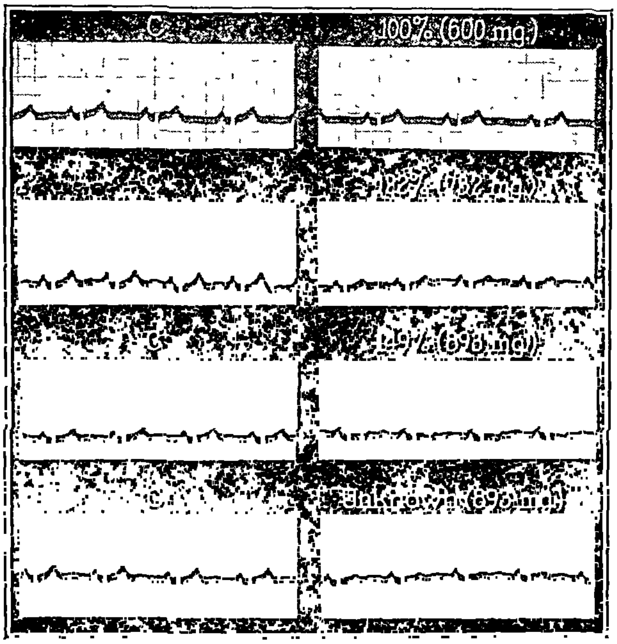

Fig. 7.—Method of digitalis assay in human beings. *C* is control, dose is given orally, and tracing is taken twenty-four hours later. The tracings are matched and ranked. Note that in this case the effect of the unknown falls between the effects of *732* and *893* mg. of the calibrating doses of the Standard digitalis.

Cumulation.—The term cumulation is widely applied to the action of the digitalis bodies. It is usually taken to refer to the fact that, if a particular dose which in itself causes little or no effect is given repeatedly, an effect will soon appear and increase in intensity as the dose is continued. There is considerable controversy concerning the precise nature of the phenomenon. We have made some observations which suggest that it represents gradual accumulation of the drug resulting from the fact that elimination falls behind. The behavior of the phenomenon resembles closely the cumulation of other drugs which are slowly excreted, such, for example, as the bromides. If one gives a dose of sodium bromide daily, say about 1 Gm., the bromide concentration of the blood begins to rise, going up to 5, 10, 20, 30, 40 mg. per hundred cubic centimeters. As the dose is continued, however, the cumulation soon comes to an end and the blood concentration continues at that level no matter how long the daily dose of bromide is continued. Cumulation is therefore a self-limiting process when a fixed daily dose is administered. The same is true of digitalis, although we do not determine it in terms of milligrams of drug but in terms of a pharmacologic effect.[12] Figure 13 illustrates this phenomenon. It shows the rate changes in a group of patients with auricular fibrillation. They received a single daily dose of 0.2 mg. of digitoxin. As the dose was repeated, the ventricular rate began to decline. It continued to fall for a period of about two to three weeks, after which it leveled off even though the dose was continued for eight or ten weeks longer. It is clear, therefore, that a fixed daily dose of digitalis produces cumulative effects which are self limiting in

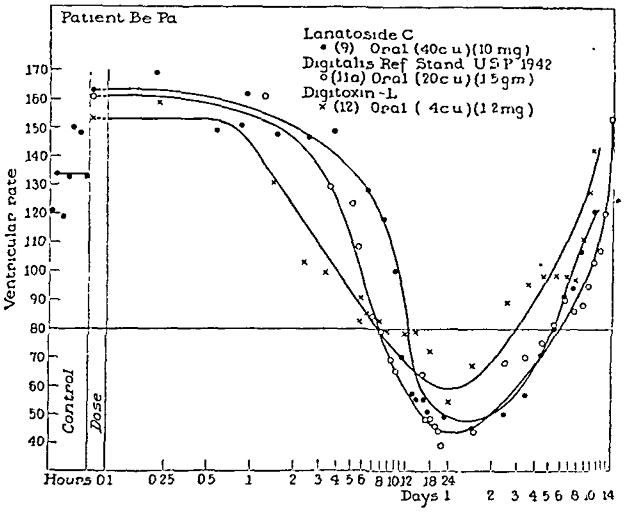

Fig. 8.—Absorption of several digitalis materials in patient with heart failure and auricular fibrillation. Note that substantially similar effects result from *4* cat units of digitoxin, *20* of digitalis leaf and *40* of lanatoside C, owing to differences in absorption.

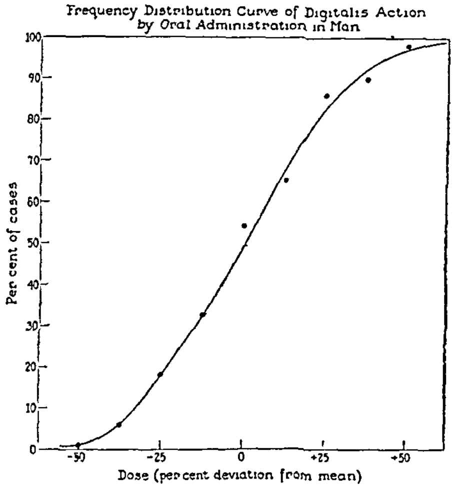

Fig. 9.—Note that the most tolerant patient with heart disease requires about three times as large a dose as the most susceptible one. Curve is based on T wave change seen twenty-four hours after the dose.

a manner similar to that of the bromides. When the dose was discontinued, the effects began to wear off and disappeared completely in about three weeks, resembling in this respect the effects of one large dose such as we have already seen in some of the previous charts.

The time it takes to reach the level varies with different drugs. In the case of quinidine, a fixed daily dose shows increasing effects during only the first three or four days. The effect then levels off, so that the continued use of that dose for months fails to produce any greater effects.

The practical importance of this phenomenon is clear enough. In the use of digitalis the patient receiving a fixed daily dose needs to be observed for from two to three weeks for signs of increasing intensity of action that may lead to poisoning. On the other hand, in the case of quinidine it is only a matter of a few days. If the fixed daily dose does not produce the desired therapeutic effects or poisoning within three or four days it is very unlikely that it will do either if continued for months unless the dose is increased, since the highest concentration on a fixed daily dose is reached within a few days in the case of this drug.

Comparison of Drugs.—I have described the method of assay of digitalis. In principle it means simply determining by how much one preparation is stronger than another, the standard preparation. Materials other than digitalis present the same problems. Let us see what has happened in the case of the cinchona alkaloids, which are of special interest at the present time to the National Research Council and the U. S. Pharmacopeia, having under consideration the substitution of synthetic or dihydroquinidine for quinidine of natural source. Frey[13] in some clinical observations in 1918 showed that quinidine is more effective than quinine in abolishing auricular fibrillation. Lewis and his collaborators[14] in 1921 made experiments in which the difference received a quantitative expression. Their conclusion that quinidine is five to ten times as effective as quinine in slowing the circus movement in the auricle has been widely quoted in the textbooks in the last twenty-five years. The implication is that all one needs to do is to give five to ten times as much in order to obtain the same results. Figure 14 is a chart which we constructed from some of their data. They found that as the dose of quinidine was increased the effect increased, but at about 0.8 Gm. a ceiling was reached. If two compounds are compared at the dosage level of 0.8 Gm. or larger, and the effects are the same, one may still be many times as potent as the other, but the difference escapes detection because, at the ceiling effect, differences cannot be revealed. And it is at this very level of dosage, namely 0.8 Gm., that Lewis and his collaborators compared these drugs.

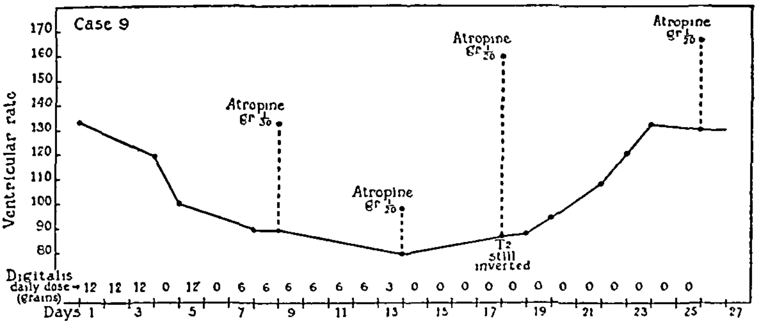

Fig 10.—Effect of atropine on the cardiac slowing caused by digitalis in patient with auricular fibrillation and heart failure varies with the degree of digitalization

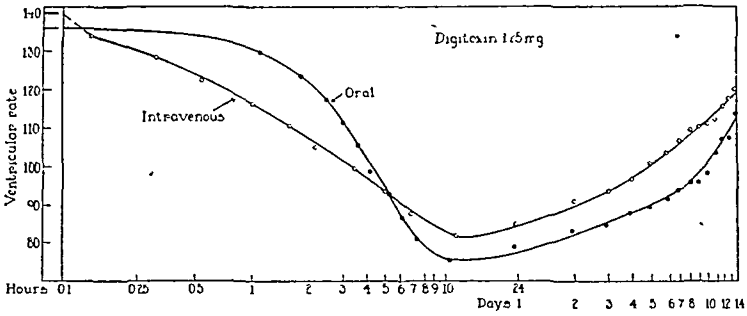

Fig 11.—Comparison of digitoxin by oral administration and intravenous injection in patients with heart failure and auricular fibrillation. Time is charted in hours after the dose. Curves represent the average results with 9 (oral) and 14 (intravenous) patients

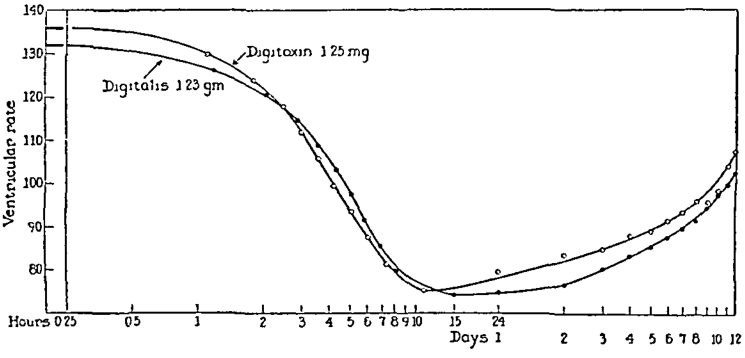

Fig 12.—Comparison of oral digitoxin and digitalis in 9 patients with heart failure and auricular fibrillation. The drug was given in one dose. Time is charted in hours after the dose. Note the similarity in speed of absorption and duration of action of digitalis and digitoxin.

Dosage Response Curve.—We have repeated these studies[15] with dosage response curves. Out of the preliminary experiments a somewhat different story is beginning to emerge (figs. 15 and 16). Indeed, the results confirm the observation that quinidine is more effective than quinine, gram for gram. It will be noted that as the dose is increased the effect in the case of each drug increases, and that in each case a ceiling effect is reached. But it will also be noted that the ceiling is about twice as high in the case of quinidine as for quinine. Therefore, in the range of a low grade effect, the two drugs are interchangeable. In case the therapeutic effect can be secured by an action equal to circus slowing in degrees up to 20 per cent, either drug will produce it if one uses two to three times as much quinine, but if stronger actions are necessary in the range shown by circus slowing up to 40 per cent, the two drugs are no longer interchangeable. No matter how much quinine is given it cannot match the effect of quinidine in this range. It cannot exceed its own ceiling. The case of ephedrine and epinephrine on the blood pressure would yield a similar set of results.

I wish to call attention to the fact that the comparison of drugs is a pharmacologic game with a set of rules which must be observed: The results do not come out right if the rules are ignored. The dosage response curve, which is the only means of securing information regarding the sensitive range of the physiologic measuring device, is not commonly established in the usual comparisons of drugs on the human subject.

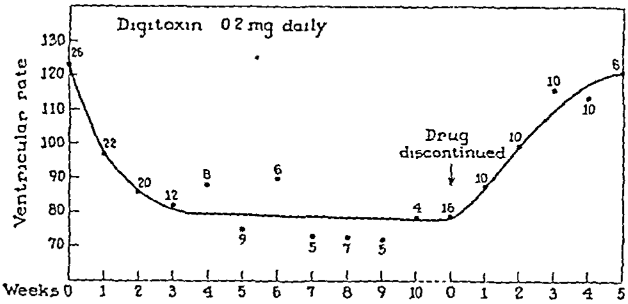

Fig. 13.—Cumulation of digitoxin in ambulant patients with heart failure and auricular fibrillation.

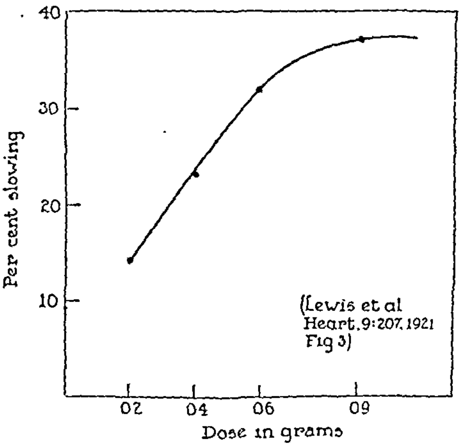

Fig. 14.—Effect of quinidine sulfate on rate of circus movement in patient with auricular fibrillation.

Dosage.—We might now turn to another matter concerning the use of cardiac drugs, namely the principles of dosage. The case of digitalis, quinidine and the mercurial diuretics may be used to illustrate my points, although it goes without saying that basic principles of dosage which operate in the case of these might well be expected to find application to therapeutics in general.

Average Dose.—I have already discussed the use of digitalis in the form of an average digitalizing dose given at one time. The term average dose is freely used in the clinical literature, but there is clearly need for more attention to its full meaning. It is one of the most useful units of dosage, for it represents the quantity of the drug with which a therapeutic procedure may be started. Clearly that amount cannot be expected to produce the therapeutic end point in all patients, because the susceptibility of patients varies. The utility of the average dose will differ from drug to drug. Its utility in the case of any particular drug can be determined by a study of the frequency distribution curve. If the drug in question happens to be one in which the curve is fairly steep, which means that individuals do not show very wide differences in susceptibility, the average dose is extremely valuable; for in that case the average dose will exert the specific effect or something very close to it in the large majority of people. On the other hand, if the frequency distribution curve is fairly flat it indicates that there are relatively wide differences in susceptibility from individual to individual and that satisfactory effects are not likely to be obtained from the average dose. I have pointed out how the approximate average dose is expected to behave in the case of full digitalization. That dose is based on the whole range of cardiac patients, ambulant, bed patients, those who are in moderate failure and those who are in advanced failure. Disappointments have been voiced over the fact that this dose has failed to produce the desired effects in a limited range of experiences.[16] Isn't that precisely what should be expected from any average dose? Is it to be expected that it will fit the individual case any better than an average sized hat fits any particular head?

Perhaps our experience with the average daily maintenance dose of digitalis will help to clear the point (fig. 17). This chart shows the effect of 0.2 Gm. of digitalis given daily to 40 ambulant patients with auricular fibrillation. The desired effect is to maintain a rate of 70 a minute. When this dose is given to a large group of patients for a period of four weeks the rate is rarely exactly 70 a minute for any given

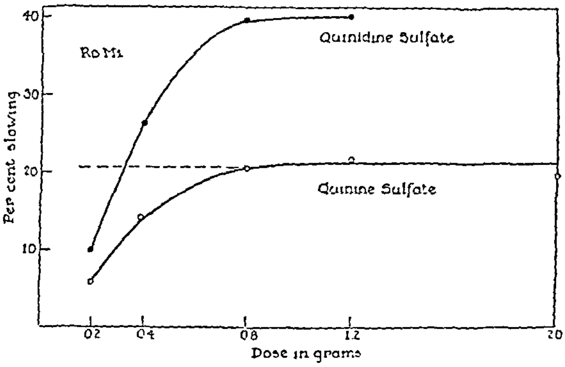

Fig. 15.—Effect on rate of circus movement in patient with auricular fibrillation. The dose of drug was given on an empty stomach and electrocardiograms were taken at two hour intervals for the greatest effect; it usually occurred in two to four hours after the dose. Interval between doses was two to three days.

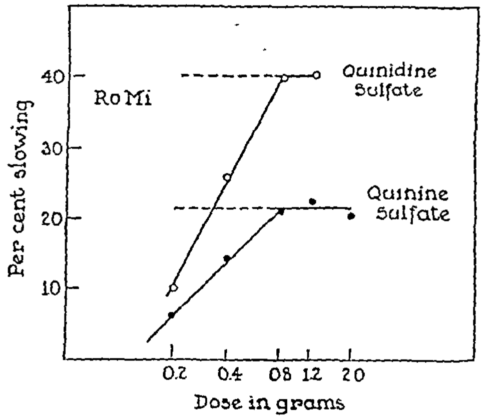

Fig. 16.—Effect on rate of circus movement in patient with auricular fibrillation. Same as figure 15 but charted in log of dose.

---

[16] DeGraff, A. C., and Batterman, R. C.: M. Clin. North America 26: 929 (May) 1942. Stewart, H. J.: New York State J. Med. 45: 1676 (Aug. 1) 1945.

patient, but a result sufficiently close to that is obtained in about 70 per cent of the group, namely a rate ranging between 60 and 90. The rest are either too tolerant and maintain rates up to 100 or faster or are so susceptible as to attain the rates of 40 or slower. That does not erase the importance of an average dose. It is still one of the most useful values in the solution of the problem of dosage. The most useful average dose, from the clinical standpoint, is one which is likely to exert an effect close enough to the desired effect, in a high proportion of patients and with reasonable freedom from toxicity. By these criteria many drugs may fail to qualify, for individual differences in susceptibility may produce too wide a scatter. Unfortunately, few drugs have been properly explored for the true position of their average dose.

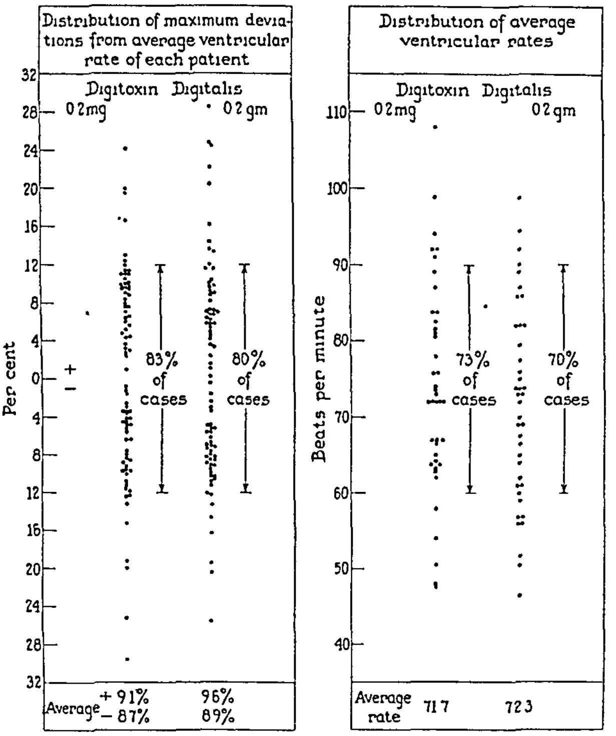

Fig. 17.—Comparison of digitoxin with digitalis in human beings (maintenance doses).

Dose for Particular Individuals.—Let us now turn from the notion of the average dose to the dose for the particular case. No one would challenge the simple statement that the optimum dose is the one which produces the maximum therapeutic effect without toxic effects. It is in the method of applying this principle that all the trouble arises. Plans of dosage are too often devised without sufficient regard to the pharmacology of the agent, its rate of absorption, cumulation and persistence of action.

Quinidine.—The case of quinidine is a good example. It is the most important agent we possess for abolishing many disorders of rhythm and for preventing their recurrence. Experiments show that its maximum absorption takes about two hours, so that the peak effect may be expected at that time and that most of the effect wears off in less than twenty-four hours. We have also found in experiments on man[17] that a fixed daily dose shows cumulation for only three or four days, unlike digitalis in which a fixed daily dose may show cumulation over a period of two or three weeks. This signifies that any daily dosage level of quinidine which fails to produce the desired effect in three or four days is likely to fail to do so no matter how long it is continued. I often encounter patients taking a small dose of quinidine for weeks on end without the slightest effect on the abnormal rhythm. The failure could have been predicted after the third or fourth day. The way of insuring success is to base the system on the facts concerning the behavior of quinidine which I have just mentioned. The method we apply in a case in which there is no urgency is to give 5 grains (0.32 Gm.) of quinidine three times daily, or 15 grains (1 Gm.) a day for four days. If the abnormal rhythm is not controlled, the dose is increased to 20 grains (1.23 Gm.) daily for four days. One continues to increase the dose by 5 grains daily every four days until a daily level is reached at which the abnormal rhythm goes or until minor toxic effects preclude its further use. If there is great urgency, as in some cases of ventricular tachycardia, one builds the concentration more rapidly on the peak effect of each dose. In such a case we use 5 or 10 grains every two hours. The total dose in the day may be small or large, but even if large it is without danger because the method has its own protective device, for the dose is continued only until the therapeutic effects occur or minor toxic effects necessitate interruption. By this method failures are few.

Mercurial Diuretics.—The tendency to overlook the principles of dosage which have gone far in establishing sound and effective digitalis therapy is particularly noteworthy in the current application of the mercurial diuretics in the treatment of heart failure. These materials, mercupurin, salyrgan with theophylline and mercuhydrin, represent one of the most noteworthy advances in cardiac therapy in the last twenty-five years. Unfortunately only a small part of the potentialities of these drugs is exploited, since they are commonly reserved only for cases in which there is frank edema or pulmonary rales occur. It deserves emphasis that, in heart failure, edema may be present in the lungs and other tissues long before the usual clinical signs, namely

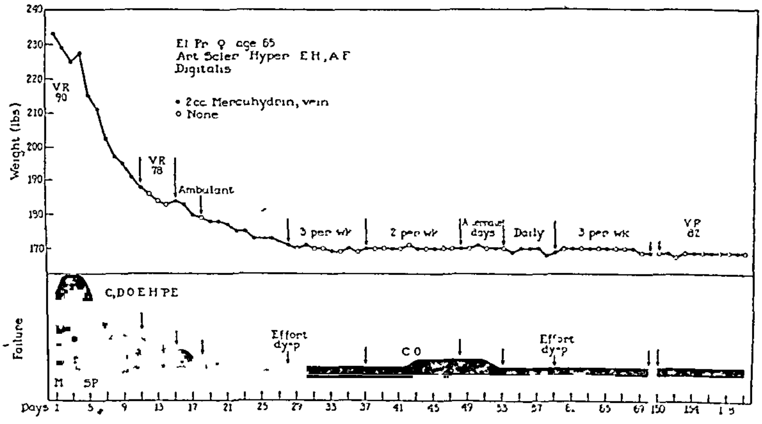

Fig. 18.—Illustration of method of producing the full effects and then establishing the maintenance dose with the mercurial diuretic in the patient with heart failure. Letters refer to symptoms (*C* cough, *D* dyspnea, *O* orthopnea, *E* edema, *H* hydrothorax, *P E*. pulmonary edema).

[17] Gold, H.; Otto, H. L., and Satchwell, H.: Am. Heart J. 9:219 (Dec.) 1933.

rales and pitting of the legs, that shortness of breath on effort, cough and orthopnea are usually much earlier signs. Patients with heart disease and these symptoms make up the largest group of potential beneficiaries of the mercurial diuretics. Furthermore, the common system of dosage calls for an injection not more often than once in four to seven days, with discontinuance of the drug until edema reaccumulates. It reminds one of the therapy with digitalis around the turn of the century; a course of treatment was given and repeated when signs of failure reappeared. The notion of the maintenance dose to prevent recurrence of failure is of relatively recent vintage. The very mention of a maintenance dose in the case of the mercurial diuretics sometimes gives rise to all the stir and alarm of a new idea. As to dosage, one should note that the organic mercurials are usually eliminated completely or almost so in less than twenty-four hours. A dose may therefore be repeated every day with safety, and, indeed, in cases of advanced failure the results of the daily dose to abolish the failure, and the maintenance dose at suitable intervals to prevent its recurrence, provide us with one of the most dramatic aspects of modern cardiac therapy.[18]

Figure 18 shows how this system may be put into operation. This patient, who was in progressive failure for several years, was now in what appeared to be the very last stages; nearly moribund, gasping for breath, edema from the toes to the neck, the liver to the umbilicus, hydrothorax and ascites, cold and clammy sweat. She had received all the necessary drugs, namely digitalis and mercupurin. She was digitalized to the point of persistent vomiting. She had received several infrequent doses of mercupurin, which seemed to increase the urine output but made the symptoms worse, as a result of which it was discontinued. When she failed to rally she received the last rites. It required much persuasion to secure the privilege of subjecting this patient to a daily dose of the mercurial when doom seemed so certain. From the character of the symptoms, doom seemed no less certain in the first five days of treatment. The only encouragement came from the daily body weight. It began to decline from the very start. There was a long lag in the symptoms; they showed distinct improvement only after a loss of nearly 20 pounds (9 Kg.). When the daily dose was interrupted the improvement was halted. In seventeen days the patient was ambulant and nearly free from symptoms. She had lost about 65 pounds (29.5 Kg.) to reach her "dry weight." The method of trial and error established the maintenance dose, namely the dose which served to maintain the "dry weight." It turned out to be one dose three times a week. At the time of this chart it had been in use for about four months; it is now more than a year. It is noteworthy that in the case of the mercurial diuretics an accurate chart of the body weight may be put to substantially the same use as the heart rate for the patient with auricular fibrillation treated with digitalis, or the fever chart in the case of infection treated with penicillin.

Smoke.—There exists a direct and highly significant relationship between air pollution and infectious diseases of the respiratory tract in man. This hazard involves principally the men living in the most heavily industrialized city districts and breathing its polluted air. In its overall aspects this respiratory disease situation is probably fully comparable in severity with the enteric disease picture so completely altered long ago by city water purification.—Mills, Clarence A.: The Relationship of Smoke to Infections of the Respiratory System, *Cincinnati Journal of Medicine*, September 1946.

MODERN CONCEPT OF THE NEUROSES

KARL M. BOWMAN, M.D.
San Francisco

It is conservatively estimated that 50 per cent of all cases seen in general medical clinics are primarily psychiatric problems, most of which would be labeled neuroses. A prominent cardiologist has stated that over half the cases referred to him are cardiac neuroses and not organic heart disease. If, then, the neuroses are seen so frequently in all fields of medicine, it seems desirable to present a paper on the subject before this audience.

There is no commonly accepted definition of the term neurosis. Some of the older writers differentiated carefully between the neuroses, which were considered organic diseases with a definite physical basis, and psychoneuroses, which were thought to be of mixed origin with the psychologic factors regarded as the more important ones. Beard described neurasthenia as due to an organic nervous exhaustion.

Freud originally separated the true neuroses, which he felt were physiologic in origin. In his earlier writings he described neurasthenia as follows: "Pure neurasthenia, which after it has been differentiated from anxiety-neurosis presents a monotonous clinical picture (exhaustion, sense of pressure on the head, flatulent dyspepsia, constipation, spinal paraesthesias, sexual weakness, etc.) admits of only two specific aetiological factors, excessive onanism and spontaneous emission. . . ."

Modern medical practice makes the use of the terms neurosis and psychoneurosis almost interchangeable. There are, however, numerous papers which use the term neurosis in a more organic fashion. For example, a recent article by Bennett devotes several pages to what are called the vasomotor neuroses. Such conditions as erythromelalgia, causalgia and scleroderma are included. Until more is known about the etiology of such diseases, the term neurosis will continue to be used for clear-cut organic syndromes and for borderline conditions as well as for those of psychologic origin. In the present paper the terms neurosis and psychoneurosis will be used interchangeably.

Time does not permit discussing the historical development of the various concepts of the neuroses. Two illustrations may be of interest in showing that the modern concept of sexual repression as a factor in the production of hysteria was well recognized by the ancient Greeks. Over 2,000 years ago Plato wrote: "The matrix is an animal that longs to generate children. When it remains barren for a long time after puberty it feels it difficult to bear, it feels wroth, it goes about the whole body closing the issues for the air, stopping the respiration, putting the body into extreme dangers, and occasioning various diseases, until desire and love, bringing man and woman together, make a fruit and gather it as from a tree."

Hippocrates thought that temperament depended on the four humors—blood, black bile, yellow bile and phlegm—and that the corresponding temperaments were sanguine, melancholic, choleric and phlegmatic. One of his women patients was thought to have hysteria due to "a dislocation of the humors." He recommended that she be treated by "indulging the intentions of nature and lighting the torch of Hymen."

Throughout history one finds various descriptions and interpretations of the psychoneuroses. The religious point of view held sway for a great deal of this time, and persons were regarded either as great religious leaders or as possessed of the devil, depending on the particular conditions that prevailed at that time. During the witchcraft scares of the sixteenth century a spot of hysterical anesthesia was known as the witch's claw and was supposed to indicate the spot where the devil had touched the person in sealing the compact whereby he sold his soul to the devil. It is only during the last one hundred years that there has been a general recognition of the neuroses as a form of sickness belonging to the field of medicine. Even today there are those who deny that such is the case and feel that these problems belong to religion, education, psychology or some other field.

Starting with the work of Charcot, Janet, Breuer and Freud, and followed shortly after with the work of Adolf Meyer, there has been built gradually a large amount of scientific knowledge concerning these disorders. Even today there is no common agreement among members of the medical profession or even among psychiatrists concerning many of the formulations. At present, however, the generally accepted approach is the biologic approach. Man is regarded as a highly complex and constantly changing organism, adjusting to a highly complex and constantly changing environment. He can be studied and understood by all the methods employed in studying other organisms. He can only be understood as a social being who lives in a society and a culture which determine his attitudes and behavior. His capacities and limitations are determined by heredity, and as a being of living protoplasm he is affected by the physical factors of his environment. There are, therefore, an almost limitless number of variables which determine his behavior and which may produce maladjustment.

Mental disease, like all disease, may be regarded as a failure of the organism to adjust adequately to its environment. All disease is an indication that the organism is incapable of adapting itself to the demands of life. Mental disease is not something for which one is to be praised or condemned; it is a medical, not a moral, problem.

There is a great variety of mental disorders, each with different symptoms and causes. Some are benign; others are malignant. The more serious mental disorders are called psychoses. The terms minor psychosis, neurosis or psychoneurosis are given to a group of milder mental disorders. Such a descriptive term as minor psychosis is, in my opinion, useful and does give the correct concept of the nature of a psychoneurosis. If one attempts to describe a psychoneurosis in terms of the reaction or behavior of the patient, one is at once involved in difficulties in differentiating between a so-called true psychoneurosis and a psychoneurotic reaction as a part or symptom of some other disease.

Early brain tumors, for example, are often diagnosed as psychoneurosis or hysteria. The reason for this is that certain symptoms of a psychoneurotic type are present. At the time of examination no organic or neurologic signs can be detected. By a process of exclusion the patient is labeled psychoneurotic. This

---

Read in the General Scientific Meetings at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 2, 1946.

diagnosis of psychoneurosis on the basis of no apparent organic cause is a common practice open to considerable criticism. A diagnosis of psychoneurosis should be on a positive basis and not merely on a negative one. The fact that no organic sign can be detected does not mean that one is not present which is the essential cause of the patient's reactions. It must be realized that in the early stages of many serious organic brain diseases such as general paresis, multiple sclerosis and brain tumor, the physician may encounter a syndrome which appears to be that of a psychoneurosis. It has also been shown that with dietary deficiency, especially of vitamin B_1, a psychoneurotic syndrome may be produced.

The first question is, should these conditions be labeled psychoneurosis or should use of the term be restricted to those manifestations without any organic basis? Assuming that one wishes to restrict it to those of psychogenic origin, one is immediately confronted with the so-called mixed picture. This question comes up particularly in cases of delayed recovery. Work carried on at the Langley Porter Clinic by Ruesch and his associates indicates that delay in recovery from head injury, thyroidectomy and ulcer is often determined not by the severity of the disease itself but by the psychologic attitude of the patient.

Sometimes the term "nervous disorder" is heard. It is used in two senses: first, to indicate a neurologic disorder, such as multiple sclerosis, and second, to indicate a mild type of mental disorder. Families will say "There is nothing wrong with him mentally, he is just nervous." There are those who call the neuroses "nervous disorders or a nervous breakdown" and insist they are not mental disorders.

Janet once said that the only difference between the neuroses and the psychoses was how much money a patient had. If he had plenty of money he remained at home with private nurses and was said to have a nervous breakdown. If he had no money he was sent (to quote Janet) to "a lunatic asylum" and was said to have a psychosis.

There is no satisfactory simple definition of a psychoneurosis. The symptoms are extremely variable, and a large percentage of them are merely exaggerations of responses which all normal persons have. In fact, one attempt at defining psychoneurosis is to say that a person is a psychoneurotic, who habitually behaves in a psychoneurotic fashion. All persons at times behave this way. This concept would indicate that there is no fundamental difference between the psychoneurotic and the normal person. The difference is quantitative rather than qualitative.

Another way of dealing with the problem is to speak of the psychoneurotic syndrome, or, following Adolf Meyer's concept, to speak of the psychoneurotic reaction type. Such a method avoids considering the psychoneuroses as clear-cut disease entities. It rather regards them as a series of varying types of reaction brought about by multiple causative factors which vary from case to case. For those who consider the psychoneuroses as disease entities, there is no question of a single disease, but rather of a large number of diseases with different symptomatology and different causation. Thus neurasthenia and hysteria have for a long time been regarded as fairly clean-cut entities with a specific set of symptoms, and, by many, with clear-cut but different etiologies. The modern concepts of psychiatry have attempted to solve this dilemma by doing away with the dichotomy of mind and body. Psyche and soma, or mind and body, are considered merely as partial aspects of the total personality. It is even held that there is no such thing as a purely psychologic or a purely physiologic process. This has led to some of the present concepts often referred to under psychosomatic medicine; formulations which attempt to explain physical symptoms on an emotional basis. There has been a general inclination to think in terms of a single causation. This has varied from the concept of sexual frustration to the most recent formulation of anxiety.

Based on war experiences, there has developed an over-simplified formulation of the psychoneuroses. Under the new Army classification of psychoneurotic disorders a whole series of reactions are given, but the essential factor stressed in all cases is that they arise in persons already sensitized or conditioned by repressed childhood experiences. It is felt that a return of the original symptomatology may be precipitated by any acute emotional trauma. Anxiety is considered the core of all psychoneurotic reactions. The person is aware of this anxiety, feels threatened by it and endeavors to handle it by various methods. The conversion reaction or conversion hysteria results in the conversion of anxiety into functions of the organs or parts of the body. An attempt is made to differentiate this from what are called somatization reactions. In these latter conditions it is felt that the anxiety becomes attached to visceral organs through the autonomic nervous system, whereas conversion hysteria is thought of as a symbolic reaction affecting organs under conscious control.

The so-called organ neuroses as well as many conditions studied under psychosomatic medicine fall into this somatization group. Against all attempts to simplify the neuroses and bring in some single common factor, there is the view which probably comes principally from Adolf Meyer. This view holds that there is a plurality of causes, and that each case is highly individual and must, therefore, be studied not in the light of some preconceived concept of a simple etiology, but rather in the light of the entire life history of the patient.

There is much controversy with regard to the role of heredity and constitutional factors in causing neuroses. Some consider constitution the all important cause and feel that psychoneurotics are born, not made. Others regard constitution as of little importance. Most persons think that Freud belonged to this latter group. You may be interested in a quotation from his paper, "Heredity and the Aetiology of the Neuroses."

"As for the aetiology of the neuroses, I think we should recognize that the various aetiological factors, differing in their importance and in the way in which they are related to the effect they produce, may be arranged theoretically in three classes: (1) *conditions* that are indispensable for the production of the disease in question, but which are of a universal nature and occur as well in the aetiology of many other diseases. (2) *Concurrent causes* that share with the conditions in group (1) the characteristic of entering into the causation of other diseases as well as into that of the disease in question, but which are not indispensable for the production of the latter disease. (3) Specific causes just as indispensable as the first conditions but appearing only in the aetiology of the disease for which they are specific.

"Now, in the pathogenesis of the major neuroses heredity plays the part of a *condition,* potent in all cases and even indispensable in the majority of them. It cannot do without the assistance of the specific causes; but the importance of hereditary predisposition is demonstrated by the fact that the same specific causes operating on a sound person would produce no manifest pathological effect, while its presence in a predisposed person will precipitate a neurosis, the development of which will in intensity and extent be proportional to the degree of hereditary predisposition."

Another classification concerning which there is considerable difference of opinion is the so-called character neurosis. Attempts to differentiate character neurosis from psychopathic personality on the one hand and psychoneurosis on the other have led to many difficulties. The concept back of the term character neurosis is that it is primarily a personality deviation caused by conflicts and difficulties of adjustment during the early years of life. Some would class it under the psychoneuroses. It is apparent, therefore, that there is a wide divergence of opinion as to what is to be included under the term neurosis or psychoneurosis, and that even these two terms are not always used interchangeably.

CONCLUSIONS

The term neurosis is used to describe certain organic diseases involving the nervous system in which there may be no mental symptoms, to describe certain conditions of psychologic origin and, finally, to describe some mixed pictures. The term is commonly used synonymously with the words psychoneurosis, nervousness and nervous breakdown. Under the general use of this term are included several conditions which have different symptomatologies and different etiologies. One commonly distinguishes between a psychoneurosis and a psychoneurotic reaction. The true psychoneurosis is generally held to be on the basis of mental conflict, which is more or less unconscious and repressed. It is generally agreed that there is a variable constitutional factor which is large in some cases and small in others. Psychoneurosis is a method of solving life's problems; it is inferior, inadequate and unhealthy, but it is an attempt at their solution.

The psychoneurotic reactions are generally considered to be reactions with similar symptoms, which are either based on simple organic factors like vitamin B_1 deficiency, anemia or some similar process or are so brief and transitory that they are not felt to be true psychoneuroses. Combat fatigue and operational fatigue are held by many to belong to this group, since it is felt that they commonly arise in persons of fairly good constitution and if properly handled are brief and transitory reactions. The symptoms in the true psychoneuroses are extremely varied; there is commonly a mood disorder, which is usually anxiety or depression and feelings of inadequacy. The intellectual functions are seldom involved. Delusions and hallucinations seldom occur. The patient usually has some degree of insight in that he realizes that he is sick and needs help. The psychoneuroses must be differentiated on the one hand from the psychoses or more severe types of mental disorders, and on the other hand from psychopathic personalities.

The psychoses are the more serious mental disorders and correspond to what the layman calls insanity. It is a debatable question whether a psychoneurosis goes on to develop into a psychosis. The classical argument between Janet and Jung may be mentioned in this connection. Janet insisted that certain psychoneuroses went on to develop into dementia precox. Jung denied this but said that certain cases of dementia precox might start with psychoneurotic symptoms. Many organic diseases such as general paresis, cerebral arteriosclerosis and brain tumor may start with a psychoneurotic syndrome.

At the other end of the scale, it is often difficult to differentiate between what is called a character neurosis and what is known as a psychopathic personality. The concept of psychopathic personalities implies a greater degree of constitutional involvement, a character defect which is innate. The concept of character neurosis implies a deviation which has developed in relation to conditioning experiences and mental conflict. There is much controversy as to the cause of the true psychoneuroses. It is almost universally agreed that there is a constitutional factor of varying degree. There is no general agreement as to whether this is an inherited trait. The precipitating cause seems to be a mental conflict which is at a more or less unconscious level. This usually occurs in a person who has had many childhood conflicts and have given evidence of definite inadequacy and difficulty in adjustment throughout life. Organic factors of varying types may contribute to the picture. Psychoneurosis, then, should be regarded as of mixed origin and not due to a single cause. Each case should be thought of as individual in origin, and its factors must be worked out on this basis.

Diagnosis should not be made purely on the basis of the symptomatology presented. It must be remembered that early cases of organic brain disease may present a psychoneurotic syndrome long before there are any positive neurologic observations. Therefore, their absence does not make the diagnosis of psychoneurosis certain. The diagnosis should be made on a positive basis, not by exclusion. As said before, the disease commonly presents a mixed picture and the constitutional, physiologic, and psychologic factors must all be evaluated in arriving at a correct diagnosis.

Treatment should be based on securing the maximum results in the shortest time with the least amount of suffering for the patient. Time does not permit a discussion of all the different technics of psychotherapy. The present attitude of psychiatry is for shorter technics of treatment, and there are many of the psychoanalytic school who no longer argue that most patients require the hour a day, five days a week, treatment for one to two years. It has been clearly demonstrated that good clinical results can be achieved by briefer technics. One may employ hypnosis, drugs or a simple, frank discussion with the patient as a means of bringing up the fundamental problems. Whether a man is ever completely cured is an academic question which may be raised in all fields of medicine and which does not merit lengthy consideration.

In order to prevent the psychoneuroses, one would theoretically start with eugenics, but knowledge in this field is so limited that one is unable to offer much of value. From a practical point of view, the most important factors seem to be the family relationships and the culture in which one lives. Attention should be given to the development of healthier attitudes on the part of parents, and a healthier social attitude toward neuroses should be encouraged.

RECOGNITION AND TREATMENT OF EARLY VITAMIN DEFICIENCY STATES

DAVID CAYER, M.D.
Winston-Salem, N. C.

The significant role of adequate nutrition in the maintenance of health and the treatment of disease has become increasingly evident in recent years. Elaborate educational programs and costly advertising campaigns have made the public diet and vitamin conscious. Numerous surveys of eating habits and food consumption have been made in various sections of the country and have shown a high prevalence of diets which do not meet the recommended daily allowances of the National Research Council. The problems of postwar economic adjustment and the rising cost of living are increasing the food problems of the large group of wage earners with fixed incomes. (Reports from abroad tell of a famine of almost worldwide proportions and unparalleled severity, and raise the question as to how much of this country's supply of grain and other food essentials can be shipped abroad without seriously reducing the American diet.)

TABLE 1.—*Factors Resulting in Avitaminosis*

Inadequate Intake
1. Anorexia, nausea, and vomiting due to gastrointestinal disorders, congestive failure, pregnancy or infectious disease
2. Self-imposed or therapeutic restriction, psychoneurosis, chronic alcoholism, fads, ignorance, poverty
3. Improper cooking and processing

Poor Absorption
1. Gastrointestinal disease, loss of mucosal integrity, hypermotility, fistulas, obstructive jaundice, Wangensteen suction
2. Vitamin deficiency, sprue syndrome

Decreased Utilization
1. Hepatic disease
2. Malignant disorders

Increased Excretion
1. Lactation
2. Parenteral fluids

Destruction
1. Alkalis, sulfonamide compounds, arsenic

Increased Requirements
1. Fever, infection, pregnancy
2. Metabolic disorders (diabetes, hyperthyroidism)
3 High carbohydrate diet, large doses of a single purified vitamin

There seems to be little likelihood that the severe deficiency diseases seen in the past years will reappear. The progressive decrease in the number of patients exhibiting beriberi, scurvy and pellagra is familiar to all and can be verified by statistics from any state board of health. This decreasing frequency of frank deficiency states has focused attention on early or "subclinical" avitaminosis. It would seem reasonable to assume that all grades of vitamin deficiencies exist, from those exhibiting the characteristic clinical features of beriberi, scurvy and pellagra to those totally unrecognizable by present diagnostic methods. The chief concern of physicians at present is with this latter group of patients, who have suggestive symptoms but no tissue changes recognizable by physical examination. Since the deficiencies most commonly seen are those of the B complex, this discussion will emphasize the recognition and treatment of early deficiencies of the B complex.

DIAGNOSIS

Recognition of Factors Predisposing to Deficiency States.—Since avitaminosis may be produced by several mechanisms (table 1), it is important first to determine by history, careful physical examination and accessory studies whether or not there is some underlying disturbance leading to faulty absorption and utilization or to increased excretion or metabolism. Often many contributing factors are found in a single patient. Any patient with gastrointestinal disease, particularly if he has anorexia or nausea, should have his previous nutritional history carefully evaluated. Whenever a history of prolonged hypermotility, loss of mucosal integrity or diarrhea is elicited, poor absorption must be considered. In such patients the resulting loss of nutritional substances increases the intestinal irritability and completes the vicious cycle.

It is well to remember that in patients with digestive disturbances who have been on greatly restricted diets or have been unable to eat adequately, deficiencies of the B complex may be precipitated by the intravenous administration of large amounts of fluids and dextrose. The water-soluble B complex may be literally washed out, and the excessive carbohydrate may induce deficiency states, particularly deficiencies of vitamin B_1. Recent work has also demonstrated that intestinal bacteria which can synthesize some of the members of the B complex may disappear after the oral administration of a sulfonamide compound, especially one of the poorly soluble types.[1] Thus it would appear that sulfonamide therapy may contribute to a deficiency of the B vitamins by depriving the patient of the amounts normally synthesized.

Dietary History.—When no underlying factors can be found to account for symptoms suggestive of vitamin deficiency, the possibility of an inadequate dietary intake must be considered, and in such cases the dietary history is of extreme importance. The grossly deficient diet can be recognized without difficulty. Particular attention should be given to patients on reduction diets and to those whose diets are highly restricted because of peptic ulcer or diabetes, or for any other reason. Patients whose diets have been questionably deficient constitute a much more difficult problem. Unfortunately, the average practitioner does not have the time to elicit a careful, detailed dietary history or the training in the methods of calculation and analysis required to interpret it. Furthermore, the patient is often an inaccurate observer, and the information obtained may be unreliable. Even the best dietary history does not take into account variations in cooking habits or defects of absorption and storage.

Physical Examination.—The earliest signs and symptoms of mild deficiency states are listed in table 2. The first physical changes caused by depletion of the B complex are probably those involving the tongue and the

[1] Najjar, V. A., and others: The Biosynthesis of Riboflavin in Man, J. A. M. A. **126**: 357 (Oct. 7) 1944.

mouth. The tongue usually shows an increase in color, and the fungiform papillae may appear abnormally prominent. Papillary atrophy begins on the margins of the tongue; eventually the entire tongue may become denuded, and superficial ulcers may appear. Spongy, granular hypertrophy of the gingival margins and fissures at the angles of the mouth may accompany these changes. Such findings would immediately focus attention on the possibility of avitaminosis, and they do not require any particular elaboration. It is important to recognize, however, that even these well known manifestations of vitamin deficiency are not pathognomonic. Cheilosis, which is usually ascribed to a depletion of riboflavin, may be caused by a deficiency of other members of the B complex as well, or may result from poorly fitting artificial dentures or poor oral hygiene. Similarly, changes in the tongue may not be due to a depletion of niacin alone, as is commonly believed.[2]

Diminution of vibratory sense over the extremities is often an early finding in deficiencies of the B complex. Alterations in epidermal structures are more apt to occur as a later manifestation, and may occasionally be due to a lack of vitamin A rather than to a deficiency of the B complex.

Accessory Laboratory Findings.—General laboratory data are of little help in the majority of patients with early vitamin deficiencies. The blood picture may be entirely normal, or it may show a moderate degree of anemia, which in my experience is most frequently of the normocytic, hypochromic type. Urinalysis and determinations of the total serum proteins, the albumin-globulin ratio and the basal metabolic rate may all be within normal limits. Gastric analysis and examination of the stool do not reveal any findings of specific significance. Esophagoscopy and gastroscopic studies in patients with deficiencies of the B complex usually reflect the changes which can be seen in the mouth and the tongue. Roentgenologic studies of the gastrointestinal tract following the administration of barium sulfate may reveal pooling, puddling, segmentation and loss of the pattern of the small intestines; these changes may also occur in a variety of other conditions, however.

In the past few years laboratory procedures have been devised to measure vitamin levels in the blood as well as the amounts excreted in the urine before and after a test dose of vitamins. Low levels of vitamins in the blood and urine may exist without depletion of stores in the tissues, however, and cannot always be considered proof of a physiologic deficiency. In a previous study the use of these procedures was investigated in human subjects with unquestionable deficiency disease, in patients with symptoms suggestive of an early avitaminosis and in normal controls having no complaints and no demonstrable organic disease.[3] This study showed a definite relationship between the clinical picture of the vitamin deficiency and the laboratory findings. The well recognized clinical observation that deficiencies of single vitamins are rare in man was supported by the fact that, in general, patients with unquestionable deficiency states showed lowered levels for most of the vitamins studied.

Since it is undoubtedly true that biologic and biochemical alterations precede any obvious changes in the tissue, it would appear that latent deficiency disease may be more accurately detected by the use of such biochemical and biologic tests. Unfortunately, however, such procedures still require a well equipped laboratory, and at present remain in the realm of the special investigator.

Interpretation of Symptoms.—The subjective manifestations which occur in persons with subclinical avitaminosis have been emphasized. The multiplicity of symptoms which have been ascribed to early deficiency states is seen in table 3. The similarity between these symptoms and the varying and ill defined complaints described in neurasthenia is all too obvious. It is of the utmost importance, however, to recognize that the two conditions may coexist, since neurotic persons often have food phobias and hence are likely to eat an inadequate diet. The difficulty of determining whether or not a subclinical deficiency is present in a patient with the symptoms described, combined with the fact that purified vitamin substances are relatively nontoxic even in huge doses, has often resulted in prolonged,

TABLE 2.—*Aids in the Recognition of Avitaminosis*

Vitamin	Signs	Symptoms	Accessory Laboratory Data
A	Xerosis conjunctivae, hyperkeratosis	Night blindness	Decrease in plasma A level
C	Gingival hypertrophy, anemia	Spongy bleeding gums, painful joints, subcutaneous hemorrhages	Roentgen changes in long bones, decrease in plasma C level, response to saturation test, capillary fragility
Niacin	Stomatitis, glossitis, cheilosis, papillary atrophy, nonspecific perineal lesions, urethritis, vaginitis, pellagrous dermatitis, depression, reactive psychosis	Nervousness, anorexia, diarrhea, sore mouth and tongue, epigastric burning	Decrease in urinary excretion of niacin
Riboflavin	Magenta glossitis, cheilosis, seborrhea; nasolabial folds, ears, forehead	Eyes lacrimation, photophobia, discharge; sore tongue and mouth	Vascularization of cornea, decreased urinary excretion of riboflavin
Thiamin	Central opthalmoplegia, symmetrical polyneuropathy, combined system syndromes, cardiovascular disturbances	Weakness, fatigability, paresthesias—burning, calf tenderness, edema	Nerve degeneration as shown by biopsy, decrease in urinary thiamin excretion
K	Hemorrhages, with disorders of absorption or jaundice	Bleeding	Increased prothrombin time, other evidence of hepatic disease

[3] Ruffin, J. M; Cayer, D, and Perlzweig, W. A.· The Relation Between the Clinical Picture of a Mild or Early Vitamin Deficiency and Laboratory Determinations of Vitamin Levels, J. Gastroenterology 3: 340, 1944.

The Therapeutic Trial.—It is a practice of many physicians to administer vitamins as a therapeutic test in cases in which the dietary history and the patient's symptoms would indicate an underlying deficiency state. If such a trial results in rapid disappearance of symptoms and definite improvement, the suspected diagnosis would appear to have been sound. However, mild subjective improvement in a patient having vague and poorly defined symptoms is extremely difficult to evaluate. Improvement will often follow the administration of mild sedatives, antispasmodics or even placebos. The psychic effect of therapy was emphasized in a study of 200 asymptomatic persons without evidence of organic disease, some of whom were given vitamin supplements in various forms for a period of thirty days, while the rest received placebos. The improvement noted in general well-being was the same in the two groups. Thus it appears obvious that too great a significance should not be attributed to moderate subjective improvement alone.

TREATMENT

The basic treatment of early primary deficiency states is to induce the patient to take an adequate diet, provided that he is able to eat it. Food undoubtedly contains still unrecognized factors necessary in minute amount for proper nutrition. These are not present in purified combinations of vitamins. The constituents of a well balanced diet are being increasingly emphasized and brought to the attention of the public. Table 4 shows the principal sources of the vitamins. Patients with mild avitaminosis should be advised to include in their daily diet 1 pint (0.5 liter) of milk, whole or skimmed, one serving of cheese, one to two eggs, one adequate serving of meat, fish or poultry, two leafy green vegetables and one yellow vegetable (these may be cooked or raw), one whole grain cereal with milk or cream, two slices of enriched bread with butter, fruit juice and fresh or cooked fruit. These items, if properly chosen, need not be expensive. To them the patient may add any other foods of his own choosing.

TABLE 4.—*Foods as Sources of Dietary Essentials**

A	Thiamin	Niacin	Riboflavin	C
Dairy Products: Eggs, Liver, Vegetables: Green, Yellow	Cereals, Meats	Meats	Milk	Citrus Fruits, Vegetables
Greens	Pork	Liver	Liver	Grapefruit
Carrots	Beef	Brewers' Yeast	Brewers' yeast	Oranges
Liver	Veal	Pork	Milk	Strawberries
Squash	Ham	Bran	Prunes	Cantaloupe
Sweet potato	Brewers' yeast	Salmon	Fish	Cabbage
Eggs	Whole wheat bread	Poultry	Beef	Turnips
Milk	Dried beans	Beef	Beans	Potatoes
Cheese	Peas	Peanuts	Eggs	Tomatoes
	Enriched bread		Pork	
	Oatmeal		Peas

In addition to such a diet the physician may prescribe therapeutic doses of the specific substances listed in table 5. He should be familiar with the particular product which he chooses to dispense and should compare the dosages listed on the label with the therapeutic requirements given in the table. It will be seen that the suggested therapeutic doses are five to ten times the recommended daily allowances. Since single deficiencies rarely occur in man and since the metabolic functions of the members of the B complex are closely related, this group of vitamins should always be administered together.

TABLE 5.—*Daily Dietary Allowance of Vitamins for Adults**

Vitamin	Recommended Men (70 Kg.) Moderate Activity	Recommended Nonpregnant Women (56 Kg.) Moderate Activity	Minimum	Therapeutic Dose
A, international units.	5,000	5,000	4,000	25,000
Thiamin, mg...........	1.8	1.5	1.0	10 20
Riboflavin, mg.........	2.7	2.2	2.0	5-15

Ascorbic acid, mg......	75	70	30	100 300
D, international units.	400			

* Food and Nutrition Board, National Research Council.

In cases in which actual deficiencies exist the use of potent purified vitamin compounds is usually followed by a satisfactory response within one to three weeks. A trial of brewers' yeast or whole liver is advisable when this response does not occur. If it is not effective, it may be necessary to resort to parenteral administration. No benefit can be anticipated unless an actual need for therapy exists, and there is probably no justification for continuing such treatment over long periods of time.

In this country deficiencies of the fat-soluble vitamins are relatively uncommon in adults and when they occur are usually secondary to hepatic disease or to some other disturbance of absorption. Often the disturbances of absorption can be corrected by the intramuscular administration of liver extract, although response to treatment is usually slower than in deficiencies of the B complex alone.

CONCLUSION

The clinical diagnosis of early vitamin deficiency states is often difficult, particularly when physical findings are absent. It is unwise to make such a diagnosis on the basis of symptoms alone. If a definite history of an inadequate diet is also obtained, a trial of vitamins in therapeutic doses is indicated. In patients who have an actual deficiency, a satisfactory response to oral therapy may be anticipated within one to three weeks. The diagnosis in each individual instance depends on the careful evaluation of symptoms, physical findings, accessory laboratory data and response to specific therapy.

Primary deficiency states can be avoided by the proper selection of foods in the daily diet. Low economic status or reduction in the total food intake to *provide for shipment abroad need not reduce the quali-*

tative value of the diet. An adequate diet is still obtainable in this country, even for families of low income, and in spite of reduction in the total intake to provide for shipment of food abroad.

ABSTRACT OF DISCUSSION

DR. CHARLES F. NELSON, Beverly Hills, Calif.: For the past ten years our research department has been making a study with photomicrographs showing the results of the different deficiencies on most of the tissues of the body—the bone, the retinas, the teeth, all the different glands and all the organs. My associates and I have come to the conclusion that practically every difficulty with the human race has to do with nutrition as it is related to cell chemistry. There isn't any way that one can estimate the need of vitamins by any laboratory facilities that we have to date, but we think that all patients should receive sufficient amounts and proper ratios of minerals, vitamins, proteins and sugar. Most patients are getting too much fat. I think that until physicians are familiar with this whole question of cell chemistry progress in the practice of medicine is not going to advance rapidly.

DR. H. VERN SOPER, Los Angeles: We are highly indebted to the writer of the paper. However, I feel that we are doing in vitamins and in our diets and in our nutrition the same thing that some are doing in the practice of medicine: Too much speculation on one detail rather than a broad, comprehensive view of the patients' problems as a whole. Most vitamin deficiencies must be considered the result of a dietary deficiency. The means by which we evaluate the vitamins in the body is a highly specialized field, but the supplying of vitamins alone does not make up for the physiologic shortages which usually accompany the lack of vitamins. It has been my observation, that giving large doses of vitamins to people who present the symptoms we saw here on the chart was not sufficient. We then prescribed a balanced diet which helped some; but even this was not adequate. It was not until these patients were given a very unbalanced diet especially rich in protein that satisfactory and rapid improvement was noted. I believe that if they have a dietary and vitamin deficiency an average daily requirement is not sufficient to make up for their past losses. It has been my policy to insist that persons who show vitamin and dietary deficiencies have a very high protein diet along with vitamin management. Then, inside of ten days, a decided improvement should be seen in their symptoms. I have found that a high protein breakfast is far more sustaining to the patients during the daylight hours than to have them eat their large protein meal at night and then, twelve hours later, begin the day's work.

DR. J. CRAIG BOWMAN, Upper Sandusky, Ohio: There is a thought that I want to leave with you which I brought up last year. It is that I think we should go further back than simply treating these avitaminoses with vitamins. I believe that the fundamental trouble we are having is due to depletion of our natural vitamin sources. I believe it is going to be the physician's problem to reeducate our people to the fact that we must put back into the soil many of the natural elements which we have taken out and as a consequence of which there is a lack of the proper vitamins and minerals in our food.

DR. DAVID CAYER, Winston-Salem, N. C.: In North Carolina we are intensely interested in this problem. Ten years ago, when patients with pellagra were desired for study, a form letter sent to the county health departments would provide the required number. This is no longer the case. In the past four years we have seen only 2 patients with classic, active pellagra. We attribute this improvement largely to the intake of more adequate diets. However, many persons are still taking diets considered to be inadequate. A tremendous amount of work remains to be done. As Dr. Nelson said, early changes due to a deficiency state are probably widespread in spite of the fact they are difficult to demonstrate by physical signs. We are working on that aspect of the problem now. We feel that not only can the diagnosis be made earlier, but more intelligent specific therapy can be instituted if we are able in some scientific manner to measure the actual requirements of these individuals.

COMPLICATIONS OF INTRATHECAL USE OF PENICILLIN

THEODORE C. ERICKSON, M.D.
MABEL G. MASTEN, M.D.
and
HENRY M. SUCKLE, M.D.
Madison, Wis.

The brilliant therapeutic results and the relatively rare toxic reactions from the use of penicillin have led many physicians to overlook its possible toxicity when injected directly into the subarachnoid space. Serious reactions following intracisternal and intraventricular administration, as well as complications of its intrathecal lumbar injection, have been accumulating in the literature. In spite of these reports, one still finds widespread ignorance of the toxic reactions to the intrathecal use of penicillin. These complications prompt us to describe the reactions, analyze their cause and, if possible, find means of avoiding them. With this in mind we are reporting 4 cases and analyzing them in relation to the complications reported by other authors.

REPORTS OF CASES

CASE 1.[1]—A woman aged 45 years had been ill a week with an infection of the upper respiratory tract. She was admitted to Columbia Hospital, Milwaukee, Nov. 9, 1944, with findings of staphylococcic cerebral abscess and meningitis. Intramuscular administration of sulfonamide drugs and penicillin was started immediately and continued with interruptions until Jan. 16, 1945. Fifty thousand units of penicillin in 10 cc. of isotonic solution of sodium chloride was given November 9 and again Nov. 10, 1944. Within an hour after the second intraspinal injection she complained of feeling ill, had pain in head, back and "stomach." On November 2 blood-tinged fluid and spinal block, which persisted, were found. Intrathecal injections were made November 15 and 16, 40,000 units in 6 cc. and 50,000 units in 10 cc., respectively.

A right hemiplegia developed November 12. At operation (T. C. E.) a fairly well encapsulated abscess was found in the left occipital lobe, about 1 mm. below the surface. Thick yellow pus was evacuated, a rubber catheter was inserted into the cavity, and 2,000 units of penicillin and sulfanilamide powder were applied locally.

There was dramatic response to surgical treatment, and the patient had made an almost complete recovery by November 23, at which time she was afebrile and well oriented. However, urinary retention developed, followed by pain and weakness in the legs. By November 27 she had flaccid paralysis, incontinence and a sensory defect below the distribution of the twelfth thoracic roots. A laminectomy on November 28 (T. C. E.) from the ninth thoracic to the first lumbar vertebra, inclusive, revealed extensive adhesions in the subarachnoid and subdural spaces with a complete obliteration of subarachnoid space at the tenth thoracic level. The cord at this level was swollen and pulseless, and 4 cc. of clear yellow fluid was aspirated from its interior. Improvement beginning November 30 was steady, though slow. She was discharged from the hospital March 20 with residual of the paralysis.

CASE 2.—J. R., a child aged 22 months, had been ill two weeks before she was admitted to the Methodist Hospital[2] Nov. 19, 1945, with pneumococcic meningitis. Besides intramuscular injection of penicillin, sulfadiazine and type VI pneumococcus serum she was given 15,000 units of penicillin

[2] Dr. Margaret Prouty provided the excellent résumé of the Methodist Hospital record.

in 1.5 cc. of isotonic solution of sodium chloride intrathecally daily for three days beginning November 21. Considerable improvement occurred followed by exacerbation of symptoms November 28, at which time she was given her fourth intrathecal injection of 15,000 units of penicillin in 1.5 cc. of saline solution. On November 29 she had paralysis of extraocular muscles and decided retraction of the head; she preferred to be on her side, with legs flexed. She was alert and responsive, but movements of head were painful. It was assumed that there was a reactive arachnoiditis from penicillin irritation and continued fever from sulfadiazine or penicillin administered parathecally, and all treatment was stopped. Again there was improvement, but two days later, on December 3, a relapse occurred, at which time a spinal subarachnoid block was found. When examined after transfer to the Wisconsin General Hospital on December 3 she had a weak cry and moved her extremities on painful stimuli; her rectal temperature was 103.4 F., and her pulse rate 140. Two hours later, before any treatment had been instituted, she became less responsive, had tremor of the arms and picked at the bed clothes; her extremities assumed position of flexion and her pupils did not react to light.

* The penicillin was administered in Hartmann's (lactate-Ringer) solution.
† The penicillin was administered in Ringer's solution (isotonic solution of three chlorides).
‡ The penicillin was administered in Ringer's solution; 150,000 units of rabbit serum, pneumococcus VI, was also administered.

Although her condition was obviously fulminating, rigorous therapy was continued, penicillin being injected intrathecally and intraventricularly. After the initiation of this treatment she went into a shocklike state with complete muscular flaccidity and small unreactive pupils. The subsequent temperature record showed an erratic course, usually subnormal and as low as 93 F. She died December 14.

At autopsy the brain weighed 1,000 Gm. and was wet, and the gyri were flattened. There were petechial hemorrhages over the entire surface of the brain, with a subarachnoid hemorrhage over the right temporal lobe. The base was covered with a fibropurulent exudate which extended into and obliterated the intercerebral sulci, and there was exudate in the cisterna magna. There was an abscess (4 by 4 cm.) in the left temporal lobe, one (1 by 2 cm.) in the right thalamus and a diffuse hemorrhage in the left thalamus. There was a serofibrinous purulent exudate extradurally on the posterior surface of the lumbar spinal cord. The cord was lusterless, with subarachnoid hemorrhage, and was covered with an opaque inflammatory membrane.

Case 3.—V. J. B., a man aged 20, was admitted to the Wisconsin General Hospital Sept. 20, 1945, with signs of a right cerebellar abscess, secondary to chronic otitis media and mastoiditis, necessitating emergency operation. The abscess, the result of a mixed bacterial infection, was deep in the anterior superior portion of the right cerebellum close to the brain stem. After evacuation of 15 cc. of pus, 8 cc. of penicillin solution containing 10,000 Oxford units per cubic centimeter was instilled into the abscessed cavity, and drainge was afforded by a soft rubber catheter. Immediately the patient showed signs of decerebrate rigidity, which later merged into generalized flaccid paralysis. Sulfadiazine (5 Gm.) was given parenterally and penicillin (10,000 Oxford units every three hours) intramuscularly daily from the time of operation until death, sixteen days later. Autopsy showed residuum of a drained, right cerebellar abscess, infarction of the remaining right cerebellar hemisphere, extensive subacute meningitis and ependymitis.

Case 4.—M. F., a 6 year old girl, a patient at the Wisconsin General Hospital, became ill with signs of respiratory infection on Feb. 24, 1944. Administration of sulfathiazole resulted in improvement, but two days later signs of meningitis developed, which was confirmed by spinal puncture. February 29 sulfadiazine and type III pneumococcus serum were given, and subsequent spinal taps indicated resolving meningitis. In spite of improvement in spinal fluid findings, penicillin was given intraspinally, 10,000 units in 10 cc. every twelve hours beginning March 4, for forty-eight hours. Before the first injection the spinal fluid was opalescent, the cell count was 708 and the colloidal gold reaction was 0122221000. The day following the first intrathecal injection of penicillin her head was more retracted, and the spinal fluid was thick and green; there was no block. All penicillin therapy was stopped March 7, but retraction of the head continued to increase until the occiput was almost touching the back, resulting in mechanical difficulty in swallowing. The legs were flexed, she was alert, percussion of her head was not painful, but movement of head or legs was extremely so. She was up and about on March 25, with retraction still present. By the time of discharge on April 9 the retraction had finally been overcome, and recovery was eventually complete.

COMMENT

Siegal[3] (1945) reported an instance of transverse myelopathy following recovery from meningitis, which has direct bearing on case 1 of the present report. His patient, a woman with pneumococcic meningitis, was given 10,000 units of penicillin intrathecally on the day of admission to the hospital, in addition to penicillin and sulfadiazine administered parenterally. Her condition became worse after two subsequent daily intraspinal injections of 40,000 units (1,000 units per cubic centimeter in each instance). Intraspinal therapy was continued during the second week, the intraspinal dose being reduced to 20,000 units daily. On the seventeenth day she had a complete flaccid paraplegia with retention of urine and a sensory level at the tenth thoracic dermatome. There was no evidence of block and the fluid was sterile. She recovered, but serious paralytic residuals persisted. Siegal concluded that this complication may be regarded as a natural, although rare, complication of the disease or that it may be due to intensive intraspinal penicillin therapy.

Percival Bailey[4] (1945) has reported a case of a 15 year old boy who had been ill with meningitis for a week before he received two intraspinal injections of 50,000 units of penicillin in one day. This was followed in three days by convulsions and weakness of his legs. By the twelfth day after the intrathecal administration of penicillin he had flaccid paralysis with sensory level at the tenth thoracic dermatome and spinal block. A laminectomy the twenty-sixth day after intraspinal therapy at the seventh, eighth and ninth thoracic dermatomes revealed the subarachnoid space to be completely obliterated and the spinal veins thrombosed. A biopsy of the leptomeninx showed dense scar of collagenic tissue in which inflammatory cells were entirely absent. Dr. Bailey in his comment apparently did not consider this an adverse effect of intraspinal administration of penicillin, but concluded that this represented the end stage of an inflammatory exudate which predominated in the spinal region.

Sweet and his collaborators[5] in an earlier report analyzed the mortality and morbidity of 16 cases of pneumococcic meningitis in which sulfonamide compounds and penicillin were administered parenterally and intrathecally. In this series there were 9 deaths and 7 recoveries. Among the recovered patients there were 4 instances of reactions ascribed to intrathecal action of penicillin. In each instance the lesion involved the lower segments of the spinal cord or the roots of the lumbosacral plexus, and symptoms developed between the tenth and the fourteenth day after initiation of intraspinal therapy.

Since the original report 31 additional patients with pneumococcic meningitis have been treated by Sweet[6] with careful attention to the concentration and size of dose by the intrathecal route. Of this group 16 have recovered. There has been only one complication: a patient was inadvertently given 200,000 instead of 20,000 units. In the course of a week progressive irritation with increased spinal fluid protein and eventually a subarachnoid block, developed. He recovered with some residual effects.

In another patient of Sweet's series[5] an attempt was made to secure better diffusion of the penicillin by alternately injecting it into the cisterna magna and the lumbar subarachnoid space. The cerebrospinal fluid became bloody after twelve days; the patient went into coma, and died on the nineteenth hospital day. The autopsy showed a blood clot in the cisterna magna and meningeal adhesions just below the cisterna magna. This seems of particular significance in relation to case 3, in which it appeared that the concentrated penicillin had leaked out of the cerebellar abscess cavity. The autopsy revealed an area of hemorrhagic infarction at the site of the injection of penicillin, similar to the changes observed by Russell and Beck[7] (1945) in experiments with injection of concentrated penicillin solution into the cerebral cortex of rabbits.

Although one cannot prove that the meningitis did not contribute in part to the various complications observed, the evidence is strong that the major factor in each instance was the intrathecal injection of the penicillin. In reviewing our own cases of myelopathy and those previously reported, one is impressed with several features that they have in common, notably the onset ten to seventeen days (usually ten to fourteen days) after initial intrathecal administration of penicillin and the localization of the pathologic process to the lower cord and cauda equina (the tenth thoracic dermatome was the usual level clinically). Additionally, in several instances the patient had recovered from meningitis or seemed to be on the road to recovery, usually with sterile spinal fluid, often with evidence of spinal block. Another frequently noted observation in the progress of these intraspinally treated patients has been frequent relapses, which suggests that the penicillin has sterilized the subarachnoid space but has also increased the formation of exudate, resulting in encysted infection to which penicillin does not gain access by way of either the blood stream or the spinal fluid. From the references in the literature[8] to subarachnoid block without mention of neurologic complications, one may infer that the process frequently stops short of irreversible damage.

One must note, however, that the meningeal or nervous tissue reactions to penicillin may not be strictly localized to the vicinity of the injection in the spinal canal. In case 4 there was apparently a much more widespread irritation. Similarly, there is the case reported by Forrest[9] (1945), in which paralysis developed in the upper extremity, as well as the other types of complications listed by Sweet[10] and by Walker and Johnson.[11]

[11] Walker, A. E., and Johnson, H. C.: Principles and Practice of Penicillin Therapy in Disease of the Nervous System, Ann. Surg. **122**: 1125 (Dec.) 1945.

An observation not encountered in reviewing the literature on the intrathecal administration of penicillin was the finding of an intramedullary cavity in association with the adhesive arachnoiditis in case 1. Intramedullary cavitation secondary to spinal adhesive arachnoiditis of other origin has been noted by several authors. A recent paper by Lubin[12] (1940) suggests that it is due to decreased blood supply and consequent necrosis of the central portion of the cord. It is significant that Bailey noted a thrombosis of the vessels of the spinal cord as well as arachnoiditis.

The reaction of the meninges limited to the neighborhood of the site of the intrathecal injection of penicillin suggests that concentration of the penicillin solution in the cerebrospinal fluid is the most important factor in producing this complication. Analysis of the material suggests that the reactions are more likely to occur with relatively concentrated solutions (5,000 to 50,000 units per cubic centimeter) than with dilutions of 1,000 units per cubic centimeter or less, as recommended by the Committee of the National Research Council. In case 4 radiculitis developed in the 6 year old patient following the use of 10,000 units in a volume of 10 cc., which, however, was repeated every twelve hours for forty-eight hours. In the patient reported by Siegal[2] (1946), transverse myelopathy followed the use of a solution of 1,000 units per cubic centimeter, with a daily dosage as high as 40,000 units. It is obvious that the final concentration obtained in the cerebrospinal fluid is dependent not only on the concentration of the penicillin solution but on the total dosage. That these reactions depend on the concentration of penicillin in contact with the pia-arachnoid is indicated not only by the clinical cases but by the experimental findings of Russell and Beck[7] (1945) and the work of Walker and others.[13]

SUMMARY AND CONCLUSIONS

In 4 cases complications occurred following intrathecal administration of penicillin. In 3 of these cases the penicillin had been injected intraspinally. From these cases and those previously reported it appears that the most frequent and characteristic reaction occurs in the meninges leading to adhesive spinal arachnoiditis and in the more severe cases leading to transverse myelopathy. In 1 case recovery from such a cord lesion followed decompressive laminectomy and aspiration of an intramedullary cyst. In another case, signs of damage of the brain stem occurred following the injection of penicillin into the cavity of a cerebellar abscess from which the penicillin leaked into the basal cisternae.

The important factors in the production of toxic complications are (1) concentration of penicillin solution, (2) slow diffusion of spinal fluid, (3) size of individual doses, (4) frequency of injection and (5) duration of intraspinal therapy.

The occurrence of these complications may be minimized by using a dilute solution of penicillin, by avoiding the use of a large total dosage and by limiting the number of injections to a minimum. Further, in consideration of the altered hematoencephalic barrier in disease, it is suggested that greater reliance be placed on early treatment with maximum doses of parenterally injected penicillin, and that when possible intraspinal administration be avoided.

ABSTRACT OF DISCUSSION

Dr. Irving J. Sands, Brooklyn: The authors call attention to a rather hazardous situation arising from intrathecal administration of penicillin. The use of intrathecal administration of serum began with antimeningococcus serum and later with tetanus antitoxin. With the introduction of arsphenamine thirty years ago we began to administer the drug intrathecally according to the methods of Swift, Ellis and Ogilvie. However, Dr. Bernard Sachs and his co-workers, in a paper entitled "On the Intravenous and Not the Intraspinous Administration of Arsphenamine in Neurosyphilis," called our attention to the neuropathies resulting from the use of the drug intraspinously. Our entire intraspinous therapy is based on the theory of the blood brain barrier which exists in health but which needs modification as far as disease is concerned. With the introduction of the sulfonamide drugs, antimeningococcus serum has no longer been used intraspinously. However, the introduction of penicillin has again made intraspinous therapy a method of recognized procedure. My impression gained from clinical observation is that there is no need for intrathecal administration of penicillin in meningitis. Meningococcic meningitis lends itself readily to sulfonamide therapy. The trouble that one will encounter is with pneumococcic meningitis, and in that particular type the early administration of intravenous penicillin in conjunction with sulfadiazine will cure most of the patients. Occasionally the organism will persist in the spinal fluid despite the clinical improvement of the patient. Then one may have to use intrathecal administration of penicillin. In doing so, however, one must prepare the patient properly, first by administering a hypertonic glucose solution intravenously, secondly by withdrawing two or three times the amount of spinal fluid in proportion to the solution of penicillin one wishes to inject and thirdly by diluting the solution of penicillin, giving only 20,000 units in twenty-four hours. The use of penicillin intrathecally is necessary only on rare occasions.

Dr. Benjamin Boshes, Chicago: This paper is a most important contribution to our utilization of this antibiotic agent. However, I believe that too much emphasis is placed on the negative phases of penicillin therapy. If one uses penicillin as it is suggested it be used, rather than using it in unusually large doses, many of the complications can be avoided. My experience has been exclusively with men of the Army, and perhaps a sample of army material as against civilian material is poor because the average soldier is healthy and almost hard to kill. Secondly, in the Army great emphasis is placed on the early diagnosis of meningitis, with the result that it is rarely that we see a soldier in a true meningitic state. The diagnosis is usually made in the septicemic state. Rosenberg and his group at the Great Lakes Naval Training Station reported 72 cases of meningitis of all types—meningococcic, pneumococcic and others—with cell counts up to 50,000. In his series, treating them by the intrathecal method exclusively, he had 100 per cent recovery and not a single important complication. I have spoken to Dr. Rosenberg about this group because it seemed almost fantastic, and he assures me that in following his cases there were no recurrences nor complications, except on occasional transient palsy. In our group we had exactly the same results. We saw none of the complications that have been described here. I am attributing these results to one factor only: we gave penicillin exactly as it had been suggested in our official directives. Overseas we did not have access to much literature, but our army directives in this case at least were very useful. We never gave more than 10,000 units at a time intrathecally. It was rarely that we had to repeat the administration during the day, and only in exceptional cases did we have to give more than four intrathecal injections of penicillin in all. Penicillin given as 10,000 units intrathecally, not repeated oftener than necessary, has in the hands of many been a drug without complications.

[13] Walker, A. E., and Johnson, H. C.: A Convulsive Factor in Commercial Penicillin, Arch. Surg. **50:** 69 (Jan.) 1945; A Note of Warning, J. A. M. A. **127:** 217 (Jan. 27) 1945. Walker, A. E.; Johnson, H. C., and Kollros, J. J.: Penicillin Convulsions, Surg., Gynec. & Obst. **81:** 692 (Dec.) 1945. Walker and Johnson.[11]

Dr. A. Earl Walker, Chicago: There are three main types of complications to penicillin administered directly to the central nervous system. First, the changes occurring in the arachnoid, second, the alterations in the nerve fibers, inducing a radiculitis, and, third, the cerebral reactions, taking the form of convulsions. We have found all three types to occur when penicillin has been given in large doses but practically never when the dose of penicillin has been quite small. Whether the concentration is the predominant factor is hard to determine. Certainly the total amount of penicillin seems to be more important than the actual concentration. Adequate treatment of meningitis with penicillin will depend on the amount of penicillin which actually reaches the various parts of the subarachnoid space. Experimentally in animals and in man, lumbar penicillin does not reach the subarachnoid space over the brain in very high concentrations. As a matter of fact, in some instances we have not found any penicillin in cisternal fluid after the injection of as much as 30,000 units in the lumbar region. Examinations were made of the cisternal fluid for a period of six hours after the injection. The peak is usually reached within four hours. When the injection was made in the cisternal region the distribution of the penicillin is much better. The concentration in the ventricles and in the subarachnoid space over the brain is considerably higher. Even with infections of the meninges, parenteral administration of penicillin in large doses in many instances will not produce an antibiotic concentration in the spinal fluid. It is true that for the more sensitive organisms such as the majority of the meningococci, antibiotic concentrations can be reached by parenteral administration of penicillin, but for the more resistant organisms such concentrations are not reached, and it is necessary to give penicillin intrathecally. I think Dr. Masten has pointed out that the amount of penicillin should be kept as low as possible, for certainly, even if the penicillin is given in small amounts, antibiotic concentrations may be maintained for twenty-four hours. Ten to twenty thousand units seems to be as much as the brain will tolerate in most cases.

Dr. Mabel G. Masten, Madison, Wis: I thank the discussers, with whom I am in complete agreement. I must emphasize, of course, that in regard to civilian practice we do not have the opportunity of seeing the patients as early as the military did. I have no doubt that many of Rosenberg's cases would have responded very favorably to the parenteral methods of penicillin therapy. I must admit that I have held even more nihilistic views toward intrathecal therapies, and although neither the proponents of intraspinal treatment nor I have irrefutable proof to support our views, it seems better wisdom on my part to make a compromise as has been stated in our conclusions for the purpose of achieving at least a thoughtful conservative attitude toward intrathecal injection of any agent.

Radioactive Isotopes of Iron.—The original studies of Hahn and his colleagues in animals and of Ross and Chapin in humans employed a mixture of radioactive isotopes of iron, prepared by bombardment in the cyclotron of iron phosphide. Subsequently Evans and his co-workers at the Radioactivity Center of the Massachusetts Institute of Technology developed methods for preparing two separate isotopes by bombardment of manganese and cobalt respectively. The half-life of one of these isotopes is five years; that of the other, forty-seven days. The fact that the first has its principal radiation in the form of x-rays and the second in the form of beta rays (energetic electrons) has been utilized in constructing a Geiger counting chamber with windows specifically sensitive to the radiation of each isotope. With each isotope there have been developed three products safe for human injection: (1) radioactive iron in the form of ferric ammonium citrate, (2) radioactive hemoglobin derived from the cells of patients who have received radioactive iron and (3) their red cells containing radioactive hemoglobin. —Armstrong, S. Howard, Jr.: The management of Blood Preservation and Blood Substitutes, *Bulletin of the New York Academy of Medicine*, September 1946.

THE RELATIONSHIP OF PHYSICAL MEDICINE TO GENERAL PRACTICE

GEORGE MORRIS PIERSOL, M.D.
Philadelphia

The gratifying and phenomenal progress which physical medicine has made during recent years has not been limited to an increased interest in and better understanding of this form of therapeutics. It has involved a gradual development of a much broader conception of the entire subject. This changed attitude is evidenced in the adoption of the term Physical Medicine as the appropriate designation for this field of practice, thus indicating that it is no longer restricted to treatment, since many of the procedures employed are of definite diagnostic value, particularly in the study of neuromuscular mechanisms. The term physical medicine now also includes occupational therapy, an indispensable adjunct to physical therapy. All of these activities are regarded as essential to any successful, well coordinated program of medical reconditioning. The present concept, therefore, of physical medicine, as illustrated by chart 1, includes several closely associated activities that in the aggregate comprise a special field of clinical medicine of fundamental importance and proved value.

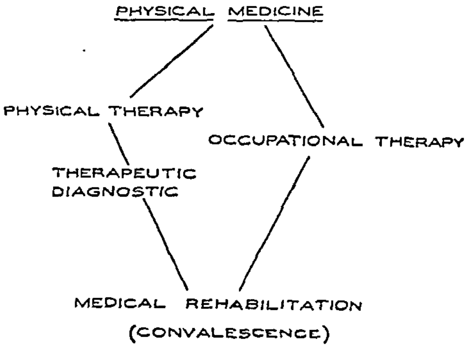

Chart 1.—The present concept of physical medicine.

In spite of the increased recognition and support which physical medicine has received from certain sources, it is a curious phenomenon that the great majority of physicians in this country have failed to show enthusiasm for or to take much interest in this branch of medicine. The reasons for this attitude have been pointed out on other occasions.[1] Suffice it to emphasize that lack of education in this subject during and after completion of the medical course is primarily responsible for this state of affairs. It is encouraging to observe that increasing efforts are being made to correct this deficiency in the medical curriculums.

There has never been a time when such exceptionally good opportunities in physical medicine have been available to the general practitioner as there are at present. The public, long aware of the value of physical forms of treatment and now acutely interested in the worldwide problem of reconditioning, is looking

toward the medical profession for leadership in this field. Thousands of the veterans returning to various communities are suffering from, and many will continue for years to suffer from, injuries and disabilities which require for their proper management physical and occupational therapy. Although a large number of those with and without service-connected disabilities will be under the supervision of the Veterans Administration, it is certain that if proposed programs are worked out, in many instances those returning from the armed forces may be cared for by physicians of their own choosing and in their community hospitals. Those veterans who during their service experience have learned the value of physical therapy will be justified in insisting on a continuation of such treatment from their family physicians. If their own physicians, on whom they depend, are unwilling or unable to furnish such expected treatment, there should be neither surprise nor dissatisfaction on the part of physicians if the veterans seek physical therapy elsewhere. Indeed, in far too many instances this is already taking place.

It is a mistake to think that problems of reeducation or reconditioning are limited to disabilities incurred as the result of war. In a great nation such as this, in which the bulk of the population comprises workers engaged in all forms of activity, the annual toll of industrial accidents far exceeds the number of the battle casualties of any war. When to this figure is added the appalling number of traffic accidents and the indeterminate number of nonindustrial accidents that occur in the home or elsewhere, the toll of civilian injuries that sooner or later require some form of reeducation reaches a staggering total. In 1940 industrial injuries alone were listed at 1,890,000. The loss of time as a result of these injuries, if deaths and permanent disabilities are included, is estimated at 233,840,000 working days, the equivalent of the full time work of 780,000 workers.[2] It has been stated that in any one year more amputations are performed as the result of industrial and civilian accidents than were carried out on the personnel of the armed forces during the entire World War II.

Regardless of any specialists involved in the management of patients in the previously enumerated groups, it is obvious that at some time during the period of their treatment and reeducation most of them will become the responsibility of their family physicians. Since in the course of their disability a large percentage will require some form of physical medicine, the general practitioner, in order to safeguard the best interests of his patients, should be in a position to prescribe or at least properly supervise whatever treatment of this type is indicated.

The reluctance of physicians to employ physical forms of treatment is in no small degree based on widespread misconceptions of what is involved in this type of therapy. It is believed that effective physical therapy requires the use of complicated and expensive apparatus. As will be emphasized later, the experience of a department of physical medicine in a general hospital shows that the contrary is true. Massage, the application of various forms of heat, therapeutic exercises, manipulation and hydrotherapy form the bulk of the treatments given. These are comparatively simple procedures which require, for the most part, no elaborate equipment and are readily adaptable for use in both office and home. However, their successful employment is dependent on: (1) a correct diagnosis; (2) an accurate anatomic knowledge of the part involved; (3) familiarity with the technics offered by physical medicine; (4) thorough understanding of the physiologic reactions which these procedures bring about in the body as a whole as well as locally, and (5) the technical skill and manual dexterity essential to the proper administration of the indicated treatments.

The physician who intends to employ physical therapy should be mindful of the statement made by Mock[3] some years ago, that 90 per cent of physical medicine in general hospitals consists of common sense and intelligent hand work. Since the most useful procedures are relatively simple and fundamental, their employment offers no insuperable difficulties to any physician who is willing to become acquainted with the indications and contraindications for their use. This can be accomplished by the study of any one of the excellent texts that are available. The practitioner will find the Handbook of Physical Medicine prepared under the supervision of the Council on Physical Medicine of the American Medical Association helpful and profitable reading.

As is the case with all therapeutic agents that bring about definite physiologic reactions, the procedures employed in physical medicine are capable of doing harm as well as good. Not only is it essential to select the proper procedure or combination of procedures, but their dosage must be regulated in regard to intensity, duration and frequency. Disappointing and at times harmful results have frequently been recorded because of lack of attention to or ignorance of these details.

The physician who intends to employ physical therapy must, therefore, know what to expect from different forms of treatment in order to intelligently prescribe the type of therapy desired. It frequently becomes necessary to do this in order to serve the best interests of patients. Although for the most part procedures in physical medicine may be carried out anywhere, there are many technics that require cumbersome special equipment and there are certain conditions the treatment of which calls for the employment of highly trained personnel who, as a rule, are seldom available except in well organized departments of physical medicine. Among the forms of treatment that are usually available only in hospitals or offices equipped for physical therapy may be mentioned underwater exercises requiring a therapeutic pool or Hubbard tank, whirlpool baths, the more elaborate forms of hydrotherapy, phototherapy, electrotherapy, mechanotherapy that employs stall bars, rings and extension devices, alternate suction pressure, venous occlusion, fever therapy and electric shock therapy, as well as other treatments that require respirators and a variety of other special therapeutic apparatus.

The prescription for physical therapy should furnish certain data that are essential to the intelligent management of the patient. A definite diagnosis should be given. It is not enough to merely mention a symptom. For example, low back pain is not a diagnosis; it may be the result of a score of conditions, many of which call for different types of physical therapy. The part to be treated should be clearly specified, and it should be stated whether the desired effect is to be general or local. There should be some mention of why the treatment is ordered and what it is intended to accomplish. The exact details of the treatment ordered should be specified, otherwise, they must be left to the judgment of the physical therapeutist. Moreover, any associated abnormality of the patient which tends to reduce his tolerance to, or modify the effect of, physical forms of therapy should be pointed out; for example, diabetes, chronic nephritis, cardiovascular disease, abnormalities of the nervous system (both organic and functional), idiosyncrasies and psychologic peculiarities. If an operation has been performed, there should be some indication as to what was done, when it was performed, what result was obtained and what precautions are indicated because of it. One form of treatment should not be persisted in indefinitely. The type of therapy should be varied according to the patient's condition. As Wright[4] points out, transitions in treatment should keep pace with changes in the pathologic processes. It is the exception rather than the rule to find that patients who are referred for physical therapy are accompanied by a helpful and informative prescription which gives the information just outlined. As a rule, requests for physical therapy are brief, ambiguous and indefinite, and leave much to the discretion and judgment of the physical therapeutist. A survey of the prescriptions coming to a department of physical medicine leads one to believe that, from the point of view of most physicians, heat and massage are synonymous with all forms of physical therapy. What has been said in reference to the proper procedure in prescribing physical therapy is equally applicable to the closely allied field, occupational therapy. These types of therapy should no longer be regarded as separate entities but rather as closely coordinated activities which supplement each other and can with advantage be prescribed together.

[2] Report of The Baruch Committee on Physical Medicine, New York, April 1944, p. 59.

[3] Mock, H. E., cited in Handbook of Physical Medicine, Chicago, American Medical Association, 1945, p. 351.

From a survey of the prescriptions which referring physicians send to a department of physical medicine, it is evident that there is a striking lack of uniformity on their part in regard to the type of treatment desired. From such a study one is forced to conclude that there is either a wide diversity of opinion as to the proper management of many conditions or that referring physicians are unaware of the possibilities offered by a department of physical medicine and unfamiliar with the physiologic effects that may be expected of various types of physical therapy. This point is well illustrated by the following examples. In a series of 235 cases of chronic arthritis referred to a department of physical medicine, no less than 16 separate and distinct forms of treatment were suggested at the time of referral. In a group of 120 various types of extremity fractures, 11 separate procedures were advocated. In 34 cases of so-called subacromial bursitis 10 types of treatment were recommended and in 214 cases of muscular pain of undetermined origin, 15 different procedures were recommended. Thus, it is apparent that in the minds of many physicians there still exists considerable confusion over what constitutes effective physical therapy.

One of the most important functions of a department of physical medicine is to take care of patients whose treatment cannot be successfully managed without the help of special apparatus and the services of a carefully trained technical staff. There are many types of patients in this category who should be so referred by the general practitioner, if the best interests of these patients are to be served and they are to be afforded the type of treatment calculated to restore their self reliance and help them to return to a productive existence. Notable in this group may be mentioned severe and complicated fractures; certain instances of injuries to the peripheral nerves and tendons that require prolonged aftercare and exact muscle reeducation; injuries to the spinal cord resulting in paraplegia, of which so many examples are to be found among the returning veterans; cerebral palsy, and the more severe types of infantile paralysis with disabling residua. In these last three groups especially, reeducation often requires not only weeks but even years of continuous supervised treatment which can be adequately given only by those trained for the purpose.

There is one aspect of the treatment of every patient who requires reconditioning and convalescent care, regardless of how the disability was acquired, which must ever be kept in mind. Psychotherapy, although not strictly speaking a subdivision of physical medicine, plays as important a role in this type of treatment as it does in all other therapeutic procedures. Although an essential and integral part of all aspects of the practice of medicine, the proper psychologic approach is important to those who suffer from disabling and disfiguring disabilities and who have to learn to live with and use various artificial devices. In the management of every patient requiring reconditioning, proper psychologic treatment rests on coordinated effort and thorough understanding between the family, nurses, physical therapeutists and all physicians concerned in their care, especially the general practitioner. In every case of disability, regardless of when or how acquired, the patient sooner or later comes to depend chiefly on the family physician for help, guidance and encouragement. The physician's mental attitude is definitely reflected in the psychology of the patient. If he advises physical therapy with any doubt or skepticism, the effectiveness of the treatment is delayed and impaired because of the lack of enthusiasm and unwillingness to cooperate shown by the patient. On the other hand, reassurance and conviction on the part of the physician that the treatment is indicated and will be successful does much to enhance its value. The importance of inspiring patients with confidence should be borne in mind by every practitioner whenever his patients are referred for physical therapy. It not infrequently happens that physicians refer a patient for physical forms of treatment not because they believe in the inherent value of the treatment but because they are impelled to do something new for a troublesome patient whose progress is unsatisfactory. If, unfortunately, the patient gets an inkling of such a mental attitude on the part of the physician, those who are entrusted with the application of physical therapy are at the start handicapped by the necessity of overcoming a serious psychic barrier.

Those seeking information in regard to what physical medicine offers as a means of treatment often ask what type of patient and what kind of disorders are suitable for physical therapy, what are the most useful technics and what results may be expected? In order to find an answer to these questions, based not on general impressions but on factual data, my associate, Dr. Steven M. Horvath, assisted by Miss Mary C. Wenck, has just completed an analysis of the material that passed through the Department of Physical Medicine of the Hospital of the University of Pennsylvania between the first of June 1945 and the first of June 1946. Since this institution is a general hospital, which handles all types of patients both medical and surgical, inpatient and outpatient, representing almost every stratum of society, it is reasonable to suppose that the material derived from such a source approximates closely the type and distribution of patients that make up the general practice of the average physician in a large city. This would not be the case if the material studied came from a special hospital, that is, one dealing largely with military or industrial casualties or one devoted to children, orthopedic or neuropsychiatric patients. The total number of patients seen in the department during the past year was 1,239; 1,083 cases were new, representing approximately 90 new patients per month. One hundred and fifty-six cases were old and carried over from the preceding year. The patients were about equally divided between those referred from the outpatient clinics and those sent to the department from the semiprivate and private rooms and referred by outside physicians.

---

[4] Wright, J.: The Physical Therapy Prescription, Physiotherapy Rev. 25: 22-27 (Jan.-Feb.) 1945.

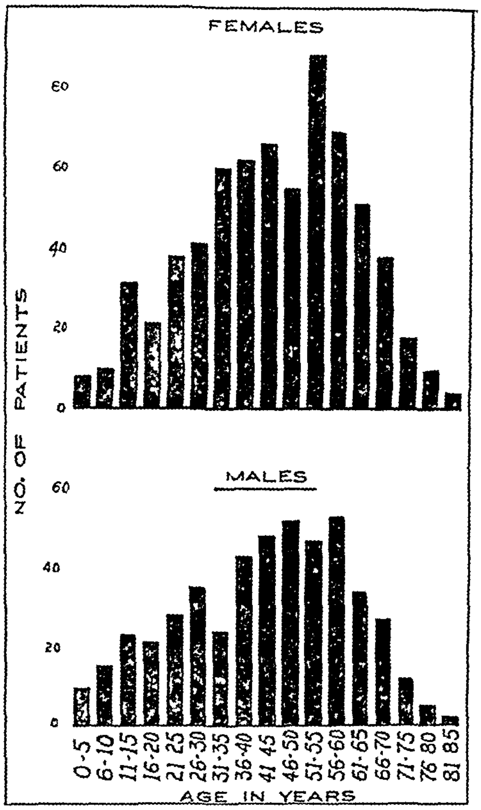

Chart 2.—Distribution by age and sex of the patients referred to the Department of Physical Medicine by all sources for one year, June 1, 1945 to June 1, 1946

The distribution by age and sex is shown on table 1 and on chart 2. There were 50 per cent more women treated than men. That physical therapy may be a useful adjunct to the treatment of patients of all ages is indicated by the fact that the age incidence ranged from 2 to 85 years. The small number of children handled is largely due to the fact that the bulk of the pediatric service at the University of Pennsylvania is carried on in a separate hospital for children. The experience of any general practitioner would undoubtedly include a greater number of young people. The number of patients in the seventh and eighth decades of life suggests that physical therapy in properly selected cases is not contraindicated in the older age groups. By far the greatest number of patients were between 40 and 65 years of age. This is the period during which the degenerative diseases such as arthritis and allied rheumatoid conditions, vascular disease, diabetes, chronic nephritis and diseases of the nervous system are most prevalent. Personal experience would lead one to believe that patients in this age group who are suffering from degenerative conditions constitute the bulk of the practice of the internist and the general practitioner.

Table 1.—*Age Distribution of Patients Treated in the Department of Physical Medicine, June 1945 to June 1946*

Age in Years	Men	Women	Totals *
0 5	9	8	17
6 10	15	10	25
11 15	23	31	54
16 20	21	21	42
21 25	28	38	66
26-30	35	41	76
31 35	24	60	84
36-40	43	62	105
41 45	48	66	114
46-50	52	55	107
51 55	47	88	135
56-60	53	69	122
61 65	34	51	85
66 70	27	38	65
71 75	12	18	30
76-80	5	10	15
81 85	2	4	6
Totals	478	670	1,148

* The age of 70 women and 21 men was unknown A total of 1,239 patients were treated, 156 being carried over from the previous year

Based on the referral diagnosis, it will be seen that 57 per cent of the conditions most often treated were represented by chronic arthritis, neuromuscular pains of undiagnosed origin, strains and fractures. The frequency of the twelve diagnoses most commonly submitted is shown in table 2. The frequency of chronic arthritis in women as compared with this incidence in men is one reason why the percentage of women was greater than that of men in the total patient load. On the other hand, as might be expected, disabilities due to trauma were more commonly found in men than in women. The great variety of conditions that were regarded as suitable for physical therapy is indicated by the 111 separate diagnoses submitted with 1,239 patients, counting all types of arthritis, fractures, back pain and strains as a single unit only.

Table 2.—*Twelve Most Commonly Submitted Diagnoses in Patients Referred for Treatment to the Department of Physical Medicine, June 1, 1945 to June 1, 1946*

Diagnosis	Number of Patients	Per Cent of All Patients *	Number of Methods of Treatment Given
Arthritis	235	19.0	16
Pain (undetermined origin)	214	17.3	15
Strains	133	10.8	12
Fractures	120	9.7	11
Bursitis	34	2.7	10
Hemiplegia or paraplegia	30	2.4	10
Postoperative	28	2.3	11
Scoliosis	22	1.8	8
Neuritis	22	1.8	9
Myositis	20	1.6	8
Bell's palsy	18	1.5	8
Posture difficulties	18	1.5	4

* There were 1,239 patients

Table 3, which shows the type and frequency of treatment given to patients with various diseases, leads to some interesting conclusions. A total of 23,345 treatments were given, representing 28 different types of procedure. As pointed out earlier, such simple forms of treatment as exercise, massage, baking and heat from infra-red lamps were overwhelmingly preponderant and represented 71.7 per cent of all the treatments given. This again emphasizes the observation that the majority of the conditions in which physical forms of treatment are useful adjuncts respond satisfactorily to those procedures which are most readily available to the general practitioner and require a minimum amount of elaborate apparatus. The large number of treatments over long periods that were required by many patients confirms the well recognized fact that in order to obtain good results physical forms of therapy must be used systematically over a considerable period, except in certain acute conditions, many of which often undergo spontaneous improvement rather promptly. It is unwise to lead patients to believe that cures can be effected by a few treatments or by occasional treatments given at long intervals. This is particularly true of the most frequently employed type of physical therapy, massage, whose effectiveness, as Pemberton[5] and others have pointed out, depends largely on its prolonged and systematic use.

TABLE 3.—*Analysis of the Treatments Given to Patients by a Department of Physical Medicine During a Twelve Month Period*

Type of Treatment	No. of Treatments	% of Total Treatments	% of Patients* Receiving Treatment	Treatments Given to Patient: Mean	Treatments Given to Patient: Range	No. of Patients Treated
Massage	7,966	34.0	72.7	8.8	1 - 82	901
Baking	5,292	23.7	54.6	7.8	1 - 70	676
Exercise	1,815	7.8	16.8	8.7	1 - 85	208
Infra-red	1,439	6.2	15.3	7.6	1 - 75	189
Short wave diathermy	1,266	5.4	14.6	7.0	1 - 43	181

Irrigation, high colonic	3	0.0	0.1	3.0	0 - 3	1
Fever therapy	3	0.0	0.1	3.0	0 - 3	1

* 1,239 patients received a total of 23,345 treatments.

The evaluation of any type of treatment is admittedly difficult and subject to error, especially when it is based on clinical impressions and the subjective statements of patients rather than on controlled objective observation. This is especially true of patients referred for physical therapy, the majority of whom, as in the present instance, were suffering from chronic diseases, in which the exact cause is not too well understood and the symptoms may spontaneously undergo long periods of remission. Furthermore, most patients while under observation received other forms of treatment along with physical therapy. In the evaluation of any special form of treatment one must reckon with the ever present and highly variable psychologic factor. With so many sources of error due to uncontrolled variables, no conclusions as to the comparative value of various forms of treatment are justified. Even impressions based on clinical observation are of little actual value unless they are checked by an efficient follow-up system, which should be instituted in every department of physical medicine if it is ever hoped to compile worthwhile data on the results of therapy.

The foregoing analysis leads one to accept as true the statement by Scull[6] that the nucleus of physical therapy as a whole is the quartet of rest, heat, massage and exercise, and that nothing has been added to these in principle since the days of the ancients except irradiation, involving roentgen rays and radium. Furthermore, the number and variety of the treatments leads to the conclusion that accurate knowledge of the relative value of the various forms of therapy and of the physiologic changes which they induce is still meager, and that empiricism continues to play too large a role in the prescription of physical forms of treatment. The solution of these problems awaits the further efforts of physiologists, biophysicists and biochemists to obtain by controlled observations a more exact appraisal of the comparative value of various types of therapy and the physiologic alterations which they bring about, not only in the experimental animal but, primarily, in man.

Physical medicine has progressed to a point at which it must be considered a separate and distinct medical specialty.[7] From this it may be logically concluded that the physician who has devoted time and special study to this subject may justly be regarded as a specialist in physical medicine, occupying a position comparable to that of others especially qualified in the various fields of medicine and surgery. It has recently been suggested that the term "physiatrist" be adopted as a suitable designation for doctors who are properly qualified in this specialty. If the practicing physician will avail himself of the experience and advice of the physiatrist in the same way as he avails himself of that of the roentgenologist, the gastroenterologist, the surgeon and other qualified specialists, suitable types of physical and occupational therapy can be instituted more efficiently in appropriate cases, thereby safeguarding the best interests of the patient, minimizing the loss of time and lessening the incidence of disappointing results which sometimes bring physical therapy into disrepute. On the other hand, the specialist in physical medicine must be aware of his obligations toward the referring physician. He should insist that the latter follow the case with him concurrently, he should advise with his colleague when changes of treatment are indicated, and when the case is concluded or further physical therapy is no longer desirable, the physiatrist should make sure that the patient returns to his original physician. Closer cooperation of this kind and better understanding between the general practitioner and the specialist in physical medicine must be fostered, if the large number of patients who need physical therapy are to receive the most effective treatment.

CANITIES AND ALOPECIA IN CHILDREN ASSOCIATED WITH AVITAMINOSIS

Preliminary Report

ANTONIO PEÑA CHAVARRÍA, M.D., San José, Costa Rica
LEON GOLDMAN, M.D., Cincinnati
C. SAÉNZ-HERRERA, M.D., San José, Costa Rica
and
E. CORDERO-CARVAJAL, M.D., San José, Costa Rica

In order to understand the so-called minimal or subclinical nutritional deficiency reactions observed in the United States, it is well to consider the severe or extreme reactions which may be observed elsewhere and especially in tropical America. At the Hospital San Juan de Dios in San José, Costa Rica, special attention has been given in the past three years to the study of changes in the hair of infants and young children with severe avitaminosis. Hair disturbances have been noted especially in the severe forms of vitamin A deficiencies, pellagra, riboflavin deficiency (cheilosis), nutritional edemas, beriberi and in the mixed forms of these general types. Such extreme hair disturbances have not been seen in the nutritional disturbances in the United States according to Blankenhorn,[1] Spies [2] and Vilter.[3] In the Medical Survey of Nutrition in Newfoundland,[4] note was made of a form of change in the hair, namely a dry, lackluster hair, so-called "staring hair." A number of South African investigators (Trowell,[5] Kark,[6] Williams,[7] the Gillmans [8] and their associates [9]) have described changes in the hair associated with severe nutritional diseases in children. According to Gillman and Gillman,[8a] Trowell [5] was the first to suggest that this nutritional deficiency syndrome observed by the various authors was probably infantile pellagra. Gillman and Gillman [8a] in Johannesburg, Union of South Africa, have done extensive work in that syndrome which they also call infantile pellagra. Clinically, this is "characterized by severe edema, typical cutaneous lesions, labial and angular stomatitis, glossitis, diarrhea or steatorrhea, peculiar depigmentation of the skin over the entire body and a graying of the hair of the scalp with varying degrees of alopecia." Williams [7] in work in the Gold Coast colony has emphasized that the changes of the hair are more noticeable when the child is older, "say of 4 years in whom the condition may have become chronic; or perhaps owing to occasional improvements in the diet, and the child has had a series of relapses and recoveries." The changes in the hair which all these authors describe are similar to those which we have observed not only in the syndrome described herein, which we, too, believe to be a form of pellagra, but also in children who presented decided follicular keratoses and angular stomatitis and occasionally glossitis with no other changes as well as in children who presented generalized edema with normal blood proteins, and with no other cutaneous or mucosal reactions. True beriberi in children has been observed in Costa Rica by Peña Chavarría and his co-workers, and these changes in the hair have been observed in such children. It is possible that the changes are similar to but more severe than the dry "staring" hair observed in Newfoundland. It is our opinion, then, that canities and alopecia may occur in children with vitamin deficiency syndromes other than that described by Trowell, Kark, Williams and Gillman and Gillman. This occurrence of canities and alopecia in children is a manifestation of deficiency disease. As Williams indicated, the more striking changes of pigmentation were observed in those children with chronic conditions. However, the syndrome, from a clinical aspect, is not caused by a deficiency of any of the well known vitamins such as nicotinic acid, thiamine, riboflavin or vitamin A. According to Vilter,[3] it may be related to a deficiency of one of the less well known members of the vitamin B complex. It is curious that no similar severe reactions of the hair have been observed in adult vitamin deficiency syndromes even of the extreme types which are found so easily in Central America. For adults, presumably, Savill [10] has indicated that "diseases of the intestinal canal in particular have in many cases hastened the onset of canities." She has reported, in a few instances, gradual improvement of the hair after improvement of the systemic condition.

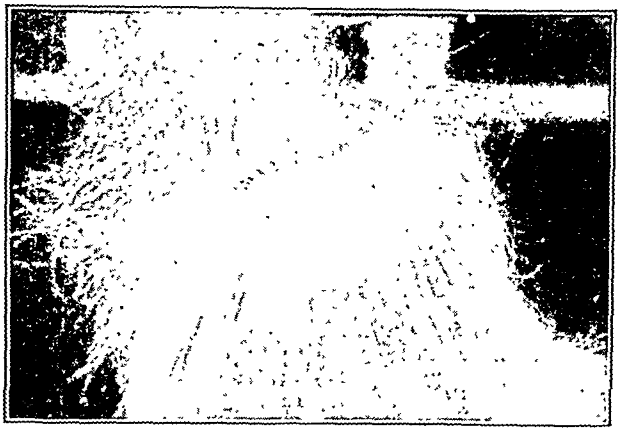

Fig. 1.—Return of pigment to the hair at proximal ends of shafts in a young girl previously ill of diarrhea and edema.

The changes in Costa Rica are observed for the most part in the hair of white and mestizo children.

These disturbances in the hair of children follow a similar pattern of development. The hair becomes dry, loses color, usually in toto, and is more fragile. It becomes loosened and is easily pulled out of the scalp. While talking to the child one can remove a handful of

hair without any pain or discomfort to the child. In some instances, the spontaneous loss of hair has been more pronounced over the frontal area and has produced on the sides the so-called "professor's corners" and in front the widened forehead, both characteristic of the idiopathic baldness in the adult.

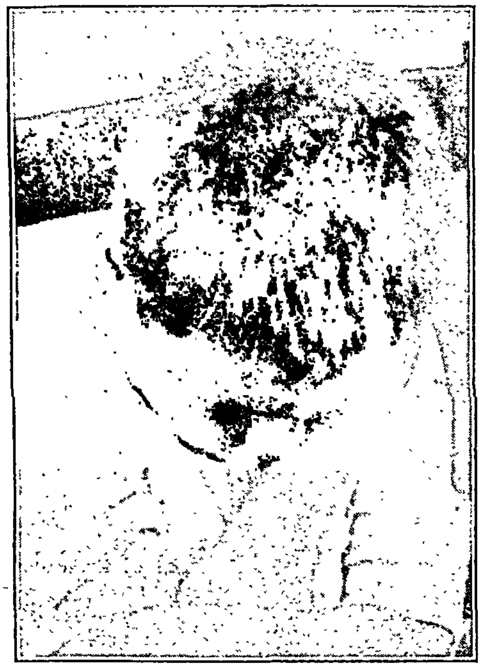

Fig. 2.—More advanced stage of return of growth and pigment in the hair of a young boy who had had follicular keratoses, angular stomatitis and glossitis.

The more interesting changes are those of depigmentation varying from slight graying of the hair to intense whiteness. This color change is diffusely spread throughout the scalp. With gradual improvement over a period of weeks to months, the pigment of the hair returns first at the scalp attachment and rapidly spreads through the shaft of the hair. The return of pigment in attached hairs may be more rapid than the return of growth in bald areas. Selected hairs were mounted and studied microscopically. The most striking feature was the depigmentation and hypopigmentation of the distal portions of the hairs. The change was gradual and was associated with spotty absence and lessened intensity of the medulla with diminishing color of the cortex, so that the distal portions of the hair presented a pale yellow, waxy appearance with only a faint trace of the medulla, only a few recognizable granules of pigment and many air spaces. The diameter, unmeasured, of the distal portions appeared lessened. The proximal portions of the hair appeared normal. Subsequent examinations of these hairs under the polarizing microscope were negative. For comparison, microscopic studies were made of the hair of a 6 year old white child with premature canities of familial origin. Biotin therapy over a period of three months had no effect on the pigment. The hair, grossly, was coarse, thin and inelastic and was entirely white. Some hairs showed bits of distal pigmentation. Under the microscope the hair showed a few scattered granules of pigment at the roots and cortex. The medulla was colorless. In general, the chief differences between these hairs and the hairs associated with the nutritional defects were that the former were coarser and harder. Sample

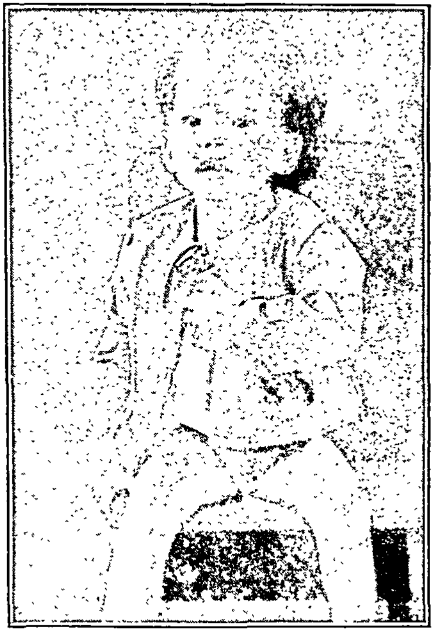

Fig. 3.—Frontal alopecia with slight canities in a child with cirrhosis and generalized edema.

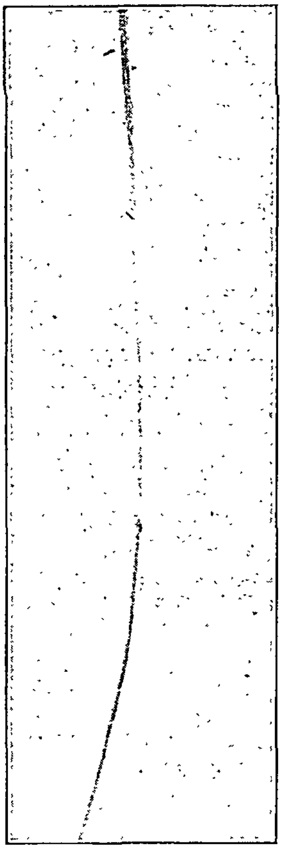

Fig. 4.—Hair of boy in figure 2 adjacent to the zone of depigmentation; the diameter had diminished, the medulla was indistinct and absent and the pigment granules in the cortex were sparser and lighter; × 10.

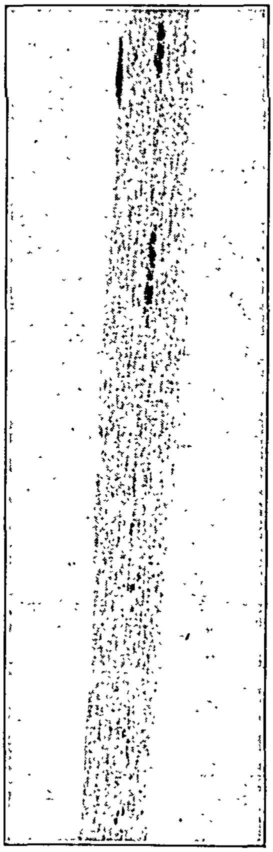

Fig. 5.—Hair of boy in figure 2 at the zone of depigmentation; the medulla is seen to be less pronounced, lighter in color and absent in portions, the pigment granules are less intense in color and more scattered. Some air spaces are also present. × 160.

hair from children in Costa Rica with the hair disturbances has been taken now and then to illustrate the progress of the return of pigment, but no controlled time measurements of growth were taken. Except for microscopic examinations, no special studies thus far have been made of these hairs. The scalp revealed slight pityriasis but no seborrheic dermatitis. Changes were observed sometimes in the eyebrows and eyelashes. As mentioned previously, associated cutaneous changes varied from normal skin to severe follicular keratoses and severe pellagrous dermatitis.

In general, records of the food intake of the children who exhibited such hair disturbances indicated a diet that consisted chiefly of bananas and molasses. Detailed analyses of the diets of these children will be published in subsequent reports.

In an effort to understand the background of these changes in the hair which would recede with improvement in the patient's general condition, various fractions of vitamin B complex were given in an uncontrolled fashion to the children. It had been observed previously that the hospital diet had effected a cure, unless the patient died shortly after admission or presented such severe reactions as diarrhea, edema, hepatosis or cirrhosis when the parenteral use of the vitamin fractions was necessary. Originally it had been planned to attempt to study the addition of such specific substances as inositol, calcium pantothenate, para-aminobenzoic acid and choline, alone and together with other fractions of the B complex. However, in addition to usual routine therapies biotin, without assay studies, was given orally, usually in doses of 0.25 mg. two or three times a day. With the addition of biotin, the return of both pigment and growth of the hair appeared to be accelerated definitely over that observed on a hospital diet or a hospital diet plus thiamine plus nicotinamide and other vitamins. These studies have been wholly uncontrolled; hence, the assumption of the more rapid action of biotin *is purely an opinion and not a proved fact.* Since similar cases of interesting changes in the hair are still available for additional studies, an effort will be made to determine, with due allowance for individual variations, the comparative accelerative effect of the various fractions of the B complex group.

CONCLUSIONS

In Costa Rica infants and young children with severe avitaminosis, especially vitamin A deficiency, pellagra, riboflavin deficiency, beriberi, nutritional edemas or mixed avitaminosis syndromes, have been observed to exhibit characteristic associated changes in the hair, both loss, diffuse or especially pronounced in the frontal area, and depigmentation. These changes in the hair resemble those reported previously by Trowell, Kark, Williams, Gillman and Gillman and others in the syndrome of infantile pellagra in South Africa. These changes are easily reversible if the patient survives the severe vitamin deficiency state. Improvement may be produced by a general, adequate diet if it is utilized alone or together with polyvitamin mixtures of the B complex.

The addition of biotin is thought, but not proved, to accelerate over other therapies the return of normal growth and pigmentation to the hair. Similar severe changes were not observed in the hair of adults with decided vitamin deficiency syndromes.

Clinical Notes, Suggestions and New Instruments

THE CONTROL OF BLEEDING DURING OPERATION BY INDUCED HYPOTENSION

W. JAMES GARDNER, M.D.
Cleveland

The olfactory groove meningioma is a benign tumor which arises from the midline of the floor of the anterior fossa of the skull, and its removal is beset with difficulties for the following reasons: First, the location of the tumor renders it relatively inaccessible; second, it is a large and vascular growth; third, its nutrient vessels come up through the base of the skull so that they are difficult to control until after the tumor is removed.

The best method of dealing with these tumors is to perform a right frontal craniotomy and to excise the portion of the right frontal lobe overlying the lateral aspect of the growth. With the electrosurgical unit the tumor is then removed in fragmentary fashion, after which the nutrient vessels in the floor of the skull at its area of attachment are treated by application of the cautery and bone wax. The loss of blood during operation may be severe. In many cases the surgeon makes extremely slow progress with the removal of the tumor until the patient's blood pressure falls as the result of loss of blood. After this occurs, bleeding from the cut surface of the tumor can be readily controlled, and the removal of the tumor goes on apace.

This was well illustrated by a patient who was operated on recently. The operation required three hours. In the first two hours less than one third of the growth had been removed. At this point the blood pressure fell from 130 to 80 because of loss of blood. Thereafter hemostasis was more readily effected, and the remainder of the tumor was quickly removed. Bleeding from the nutrient vessels coming up through the floor of the skull was then easily controlled by electrocautery, bone wax and pledgets of cotton soaked in thrombin solution. The patient received 1,500 cc. of blood during the operation, despite which the hemoglobin fell from a preoperative level of 12 Gm. to 8.9 Gm. forty-eight hours later.

For some years I have entertained the idea of lowering the patient's blood pressure by venipuncture during the first stage of these operations in order that bleeding from the tumor might be more readily controlled. Afterward the patient's own blood could be returned instead of transfusing blood from a donor. This method, however, has not been actually employed.

Kohlstaedt and Page[1] in 1943 in experiments with dogs described an ingenious method for the study of shock by arterial bleeding and infusion. Briefly, this method consists in placing a cannula in the femoral artery directed toward the heart. This cannula leads to a closed reservoir into which the dog is bled until the blood pressure is lowered to 30 mm. of mercury. The blood is mixed with an anticoagulant during its withdrawal. The arterial pressure is recorded on a kymograph. To raise the blood pressure the blood is infused into the femoral artery by the simple expedient of raising the pressure in the closed reservoir by pumping air into it.

This method permits the investigator to reduce the blood pressure to any desired level, hold it there as long as desired and then bring it back by infusion of the removed blood, provided, of course, that the animal is not permitted to go into terminal shock. In the treatment of hemorrhagic shock these authors found intra-arterial infusion more effective than intravenous.[2]

Page[3] found that the intra-arterial infusion method for the treatment of shock has several advantages. "(1) The delivery

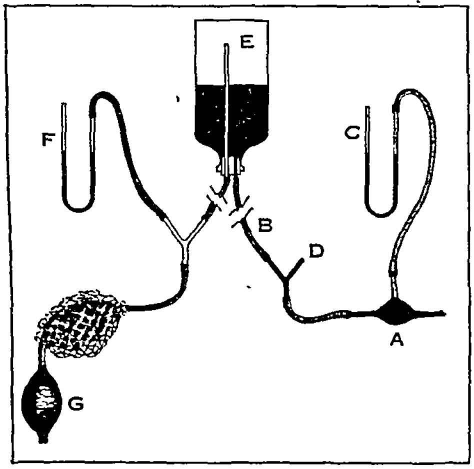
of blood into the aorta perfuses the coronary vessels, relieving myocardial ischemia and, since myocardial ischemia probably underlies the cardiac dilatation and insufficiency, places the heart rapidly in a state in which it can pump the infused blood to other areas; (2) when, before the infusion, the patient may have been apneic, at its start he will take a deep breath, as if the arterial filling had rapidly extended to the vital medullary centers; (3) in contrast with intravenous transfusion, blood pressure is rapidly restored. . . ."

In its effect, therefore, intra-arterial infusion of blood may be said to furnish the patient in shock with an accessory heart.

REPORT OF CASE

On April 3, 1946 a woman aged 49 presented herself with a complaint of blindness. She was 5 feet 2 inches (157.5 cm.) tall and weighed 280 pounds (127 Kg.). The history showed loss of sense of smell for one year. Dizzy spells began in June 1945, and it was discovered at that time that she had hypertension. In November she experienced a period of unconsciousness lasting two days, followed by frequent severe headaches and rapid failure of vision.

On examination the blood pressure was 200/130 mm. of mercury, which fell to 170/100 with rest in bed. The patient was tremendously obese, and there was bilateral optic atrophy with papilledema. She was able to see fingers with the right eye at 6 inches, and the left eye was totally blind. The sense of smell was completely absent. Roentgenologic examination of the skull showed some erosion of the posterior clinoid processes. The spinal fluid pressure was 450 mm. of water. The fluid contained 170 mg. of protein per hundred cubic centimeters. There was no evidence of renal failure. The possibility of malignant hypertension was at first entertained, but the diagnosis of olfactory groove meningioma soon became apparent.



Page procedure for induced hypotension. *A*, cannula in left dorsalis pedis artery; *B*, arm to reservoir to receive arterial blood; *C*, arm to manometer; *D*, arm to syringe with heparin solution; *E*, air space above the blood connected to *F*, another manometer, and to *G*, a rubber bulb by means of which the pressure in *E* is raised or lowered at will.

Operation was performed on April 19. With the patient under pentothal sodium anesthesia, a cannula (*A* in the illustration) was placed in the left dorsalis pedis artery directed toward the heart. One arm (*B*) of this glass cannula led to the closed reservoir to receive the arterial blood. Another arm led to a blood pressure manometer (*C*), and a third arm (*D*) to a syringe containing heparin solution. The air space (*E*) above the blood in the reservoir was connected to another manometer (*F*) and to a rubber bulb (*G*) by means of which the pressure in the air space above the blood could be raised or lowered at will. Screw or pinch clamps were used at strategic positions to control the flow of blood.

While the scalp incision was being made, 1,600 cc. of blood was allowed to flow rapidly into the reservoir, and in fifteen minutes the intra-arterial pressure fell from 140 mm. of mercury to 100. The pulse rate, which was 130 before bleeding, rose to 140. A right frontal craniotomy was performed, and the frontal lobe was elevated on a retractor. A large, soft, vascular meningioma was disclosed attached to the floor of the anterior fossa near the midline. In order to improve the surgical exposure the lower portion of the frontal lobe overlying the tumor was removed by block resection. The tumor was then removed in fragmentary fashion with the electrosurgical unit and by digital enucleation. The anterior portion was found to have straddled the crista galli and lower portion of the falx. Its posterior portion caused pressure on both optic nerves.

The tumor was extremely vascular, but despite this there was little loss of blood during the procedure. When arteries were divided, bleeding could be readily controlled by application of the electrocautery. In addition, it was noted that the blood clotted quickly, and the clot was quite firm. After removal of the growth the nutrient vessels in the floor of the skull at the area of the attachment of the tumor were readily controlled by electrocautery, and it was not necessary to use thrombin solution or bone wax to complete the hemostasis.

The pressure in the reservoir was then increased, and the patient's blood was infused into the dorsalis pedis artery. The operator waited until 1,100 cc. of blood had been infused before closing the wound. The infusion raised the intra-arterial pressure from 90 to 120 mm. of mercury and resulted in some bleeding from the scalp incision but none from the tumor bed. The wound was then closed.

When the patient arrived at the ward the pulse was 120 and the blood pressure 150/100 mm. of mercury. The tumor in this case was removed more satisfactorily and with less bleeding than in any other case in the operator's experience. The total operating time was two hours and thirty-five minutes. The actual operating time was less, because the operation was suspended for about thirty minutes to watch for recurrence of bleeding in the tumor bed during the arterial infusion. The last 500 cc. of blood in the reservoir was discarded because it had clotted as a result of insufficient heparin solution. Despite this the hemoglobin on the fourth postoperative day was only reduced to 12.0 from a preoperative level of 13.3 Gm. Convalescence was smooth except for an unexplained low grade fever which persisted for eight days after operation. Because of this fever the patient was not discharged until the thirteenth postoperative day. She was last seen ten weeks later, at which time her progress was quite satisfactory. The vision was improving, and the blood pressure was 180/100 mm. of mercury.

The experience with this method in this 1 case, therefore, was certainly encouraging, and it seems that the procedure should be given a further trial.[4]

COMMENT

Page [3] has shown that peripheral vasoconstriction is an early and constant accompaniment of shock. He has shown that during and for a short time after the initiation of shock this vasoconstriction is neurogenic due to vasomotor reflexes. As the brief period of nervous irritation passes off and unfiltrable substance appears in the plasma, which, when injected into the vessels of an isolated perfused rabbit's ear, causes severe and prolonged vasoconstriction. Thus, there is good reason to believe that the persistent nonneurogenic vasoconstriction in shock is due to the appearance of this substance in the blood. Evidence indicates that it is neither of renal nor of adrenal origin but arises from the site of tissue injury. We believe that it was chiefly this peripheral vasoconstriction rather than the reduction of blood pressure which was responsible for the ease with which hemostasis was obtained in the case reported. It is not necessary to reduce the blood pressure to a dangerously low level in order to bring the peripheral vasoconstrictor mechanism into play.

---

[4] Since its use in this original case the Page procedure or a modification of it has been employed in 6 additional cases with similar gratifying results.

SUMMARY

Hemostasis was aided during operation for brain tumor by preoperative arterial puncture and blood letting. The patient's blood was returned intra-arterially at the conclusion of the operation, thus avoiding the necessity of giving a transfusion.

DIFFUSE CALCIFICATION OF THE PANCREAS

FRANKLIN R NUZUM, M D.
Santa Bārbara, Calif.

The presence of stones within the ducts of the pancreas has been recorded in the literature in 220 instances up to the year 1944.[1] Diffuse calcification of the pancreas differs, in that the process of calcification is distributed throughout the organ, with associated destruction of the parenchyma. The organ may contain many cysts of varying size and much connective tissue; it may resemble a "bag of stones."[2] Beling[3] collected 12 reports of diffuse calcification and added 1 of his own. He and his associates later added another.[4] King and Waghelstein[5] reported 4 instances of this disease. Reviewing the reports of Beling they disagreed with the diagnosis in 2 cases which they thought were questionable. Darling[6] recorded an instance of diffuse calcification of the pancreas observed in Australia. The case herewith reported brings the number to 18

REPORT OF CASE

First Admission.—History: A white man aged 23 was admitted to the Santa Barbara Cottage Hospital in September 1944, referred to me by Dr. Artemas Strong of Santa Paula. Three years before he had been seized with "quite severe" epigastric pain over the upper half of the abdomen, associated with nausea, vomiting, diarrhea and a "low fever." He was ill for seven days. Over a period of two years similar pains occurred every four to six weeks; their duration was five to seven days. The only difference was the absence of diarrhea after the first attack. During the third year of his illness the "spells" occurred each four weeks. In 1942 a diagnosis of duodenal ulcer had been made elsewhere and confirmed by roentgen ray. He was placed on a plain diet with milk. His pain continued.

On hospitalization in August 1944 he stated that he was nauseated by all foods excepting bouillon and so had taken only that. His weight in six months had gone from 143 to 118 pounds (65 Kg. to 54 Kg.), a loss of 25 pounds (11 Kg.). His height was 5 feet 4 inches (163 cm.). He had been having daily two loose, not watery, dark brown stools. The urine was straw colored. Jaundice had not been observed.

For the past two years he had been a sprayer in a lemon orchard, using arsenate of lead. He smoked half a package of cigarets a day and used alcohol regularly, occasionally becoming intoxicated.

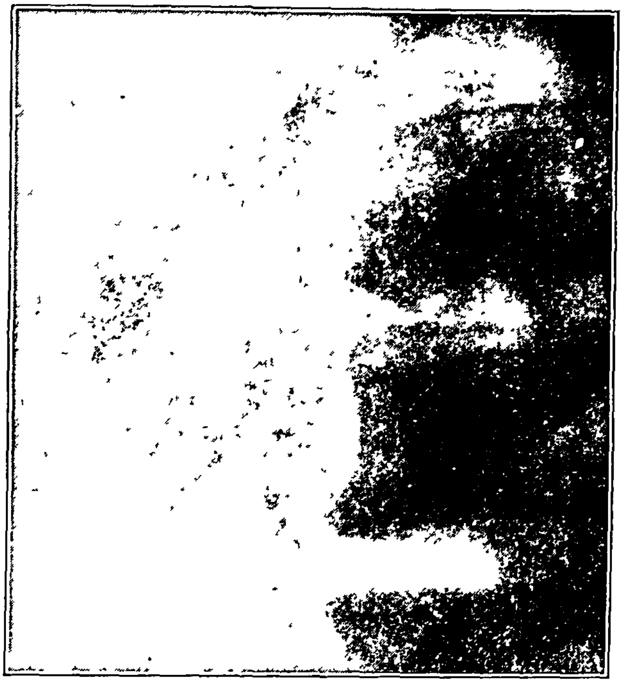
Examination: Examination revealed a dehydrated, acutely ill man, who seemed older than his 23 years. The tongue was dry and red, the gums boggy and bleeding and the teeth in need of repair. A lead line was absent The blood pressure was 122 systolic and 70 diastolic. The abdomen was moderately distended; there was much tenderness throughout the upper quadrant and the left lower quadrant. Rebound tenderness was present over the left upper quadrant. The temperature was 100 F. the first day after admission, 99 F. the second and normal or lower thereafter.

Laboratory Observations: On examination of the blood, the sedimentation rate was 20 mm in sixty minutes (Cutter); hemoglobin 77 per cent (11.7 Gm.); erythrocytes 3,600,000; leukocytes 7,800, with polymorphonuclears 82 per cent and lymphocytes 18 per cent. No basophilic punctation was found The stools were loose and dark brown, with 4 plus occult blood present.

Roentgenologic Observations: The stomach was dilated and contained fluid. The duodenal bulb was decidedly irritable and retained its barium poorly. There was pronounced segmentation of the barium mixture in the jejunal coils. After four hours there was a 60 per cent retention of barium in the stomach. The diagnosis was obstructive duodenal ulcer, deficiency state. Films of the right upper quadrant after the oral administration of priodax showed a well filled gallbladder; adequate contraction occurred under the stimulus of a fat meal. There was no evidence of calculus.

Treatment: The patient was placed on Sippy ulcer management, and he returned home.

Second Admission—History: He was readmitted to the hospital four months later, at which time he stated that after the institution of ulcer management he was free of symptoms for four weeks Pain then recurred; it started on the left side of the abdomen in the upper quadrant, radiating downward on the same side of the abdomen and down the inner side of the leg. The pain was constant, with exacerbations of severe pain which required hypodermics of morphine sulfate for relief. When not given the drug the patient walked and moved about continuously. If he sat in the same position for fifteen minutes the pain returned He also complained of constant tenderness in the left side of the abdomen His appetite was poor, and he had been nauseated and had vomited every morning for the past month.



Shadows indicating calculi in the head of the pancreas and extending across the spine into the tail

Examination: Persistent spasm was present on the left side in both the upper and lower quadrants of the abdomen, most pronounced over the left upper quadrant. The oral temperature varied from 99 to 99.2 F

Laboratory Observations: The laboratory work on this admission included examinations of the blood. The sedimentation rate (Cutter) was a 5 mm fall in 60 minutes; amylase 68 units; nonprotein nitrogen 25 mg. per hundred cubic centimeters; hemoglobin concentration 90 per cent (15.1 Gm. per hundred cubic centimeters); erythrocytes 4,500,000, and leukocytes 6,300. The percentages of the various types of leukocytes were eosinophils 4, monocytes 8 lymphocytes 26 and polymorphonuclears 62 A glucose tolerance test gave a fasting blood sugar of 94, first hour 190, second hour 195, and third hour 99 The urine contained 8 per cent, or 2 4 Gm of sugar in the second hour specimen and 0 5 per cent (0 67 Gm) in the third hour

[5] King, A. B, and Waghelstein, J. M. Calcification of the Pancreas, Arch. Int Med. **69:** 165 (Feb) 1942.

[6] Darling, H. C. R. A Case of Progressive Calcification of the Pancreas Secondary to Chronic Relapsing Pancreatitis, M. J. Australia **2:** 7 (July 4) 1942.

Roentgenologic Examination On a flat plate, throughout the bed of the pancreas there were multiple calcium shadows, indicating calcification within that region These shadows were present at the examination of Aug 15, 1944, at which time they were not recognized

Treatment The patient required frequent hypodermics of morphine sulfate, and it was evident that he needed help At operation, the distal two thirds of the pancreas was extirpated, leaving the head, which still was the seat of diffuse calcification The portion of the gland removed was the site of cysts of variable size up to 1 cm in diameter Two of these were definite abscesses

Histologic Observations On histologic examination of decalcified tissue, only a few small islands of normal pancreatic tissue were found The bulk of the organ had been replaced by dense hyaline connective tissue Between the hyaline connective tissue in many instances there were isolated islands of Langerhans

COMMENT

The etiology of calcification of the parenchyma of the pancreas is not known, although the rate of development of the calcification may be rapid King and Waghelstein[5] reported a definite increase in the amount of calcium deposited in 1 instance in eighteen months In about half the cases reported there was disease of the gallbladder with stones Beling, Baker and Marquis[4] stated that calcification follows repeated attacks of pancreatitis Pasternack[2] regards parenchymal calcification as a sequel to infection, inflammation and necrosis, quoting from the work of Edmondson and Fields[7] The role of alcoholism, apart from its apparent frequency, is speculative Like chronic gallbladder disease, it was a factor in about half of the reported instances of diffuse calcification of the pancreas Leroy Brooks[8] in a large general hospital has observed the frequence occurrence of acute pancreatitis after bouts of alcoholism in chronic alcoholic addicts William Russell[9] believes that the most likely explanation is that it represents a flare up of a healed acute pancreatic necrosis

There is no clear-cut symptom complex suggesting diffuse calcification of the pancreas Epigastric pain is the most constant symptom It may be mild or severe, intermittent or constant It may radiate to the back, to either shoulder or down into the abdomen In this patient, the pain was present in the upper half and in the entire left side of the abdomen Frequent bulky, pale stools with large amounts of fat and undigested meat fibers have been recorded This was not observed in the case reported here, and yet the pancreas was extensively diseased

Evidence of disturbed carbohydrate metabolism has been described in 45 per cent of the reported instances If glucose tolerance tests had been made in all cases, the incidence would undoubtedly have been higher Yet there is no apparent relation between the degree of destruction of pancreatic tissue and the altered carbohydrate metabolism The blood calcium level was 10 mg in this patient In some few reported instances the level has been lowered

Subsequent to operation the patient has remained free of pain Diabetes has not developed The irritability of the duodenal bulb undoubtedly resulted from pancreatic irritation

SUMMARY

Only 17 cases of diffuse calcification of the pancreas have been reported to date It is unlikely that this disease is so unusual It should be considered in the diagnosis when diffuse abdominal pain is present, and particularly when a history of repeated bouts of pancreatitis is given Roentgenologic examination of the abdomen before the ingestion of a barium meal will prove the diagnosis

Our patient made an uneventful recovery after the removal of the distal two thirds of the pancreas, and diabetes has not developed

The absence of diabetes even in the presence of widespread destruction of the gland is not incompatible with present day knowledge of the physiology of the pancreas, according to Gomori[10]

CYLINDROMA

Report of an Unusually Extensive Case

DAVID L COOPER, M D
Erie Pa

Cylindroma is a rare cutaneous affliction In the most comprehensive article on the subject written in 1933, Ronchese[1] stated that "up to 1932, only 31 fully developed cases were reported Of these, 19 occurred in females and 12 in males Since 1933, several other cases have been reported, some of which will be cited later However, it is doubtful whether more than 50 cases have been reported in all medical literature Without doubt some cases have been seen which have not been reported

The lesions of cylindroma usually occur on the scalp in the form of pink or bluish mushroom-like or pedunculated or lobulated tumors, varying in size from that of a pea to that of an apple Occasionally they are found on the extremities and trunk, there they lose their pedunculated character and appear to be embedded in the subcutis They may be of different consistency and feel firm or rubbery to the touch They often occur in several members of the family through one or more generations, they grow very slowly and are practically always benign The patients are usually in good health and in most cases are not greatly inconvenienced

NOMENCLATURE

Various synonyms have been used to describe these lesions Ronchese[1] called them multiple benign epithelioma He thought that "multiple benign familial, nodular, turban-like basal cell epithelioma of the scalp with cylindromatous degeneration" was the most complete and clear name but too long He believed that "turban tumor" was the shortest and best I believe that 'turban tumor" is the most descriptive but not the most appropriate name, for while the term 'turban" does accurately describe the Turkish headdress-like appearance of the lesions on the scalp, it does not describe the isolated and grouped lesions which may occur on the face neck extremities and body, moreover, the lesion should not be called a tumor because histologically it is a nevus growing from embryonal rests and developing later in life

Other names have been proposed Cohn[2] reported the disease of his patient as a case of multiple sarcoma Stillians[3] and Zakon[4] called it nevoepithelioma adenoides Jones, Alden and Bishop referred to their case as turban tumor or sweat gland carcinoma Gabarro[6] who reported the most extensive case in medical literature gave it still another name—epithelioma adenoides cysticum.

[6] Gabarro P An Enormous Epithelioma Adenoides Cysticum of the Scalp, Brit J Surg **33:**188 (Oct) 1945

The disease has been referred to variously by other terms—syringoma, syringocystadenoma, plexiform sarcoma, angiosarcoma, endothelioma capitis and tomato tumors.

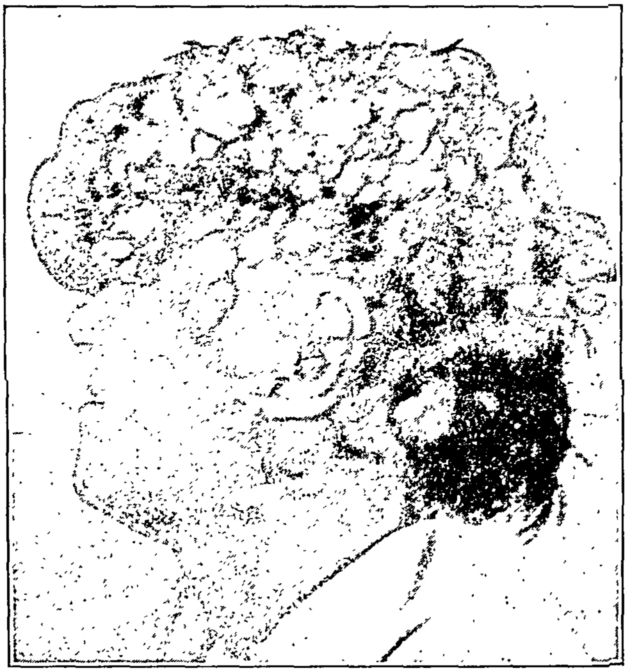

Fig. 1.—Lateral view showing grapelike and tomato-like appearance of lesions. Note involvement of the ear and neck as well as of the scalp.

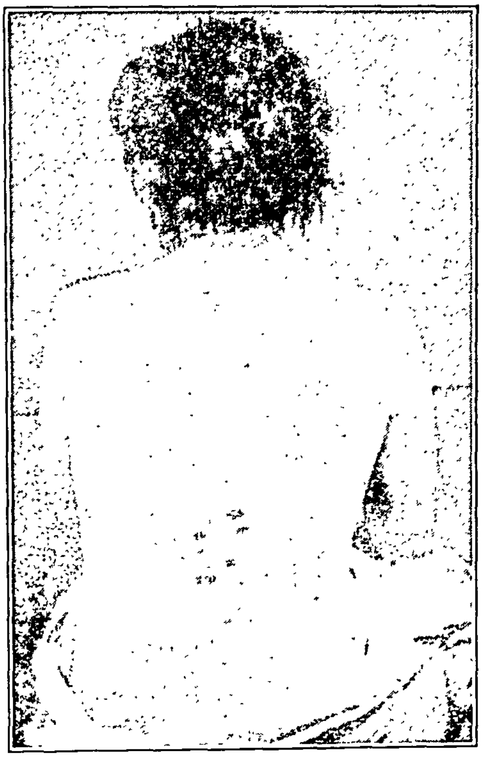

Fig. 2.—Rear view showing involvement of the back of the scalp with a small group of lesions on the lower portion of the back.

PATHOGENESIS

The lesions have been regarded as basal cell epithelioma by Frieboes, Watanabe, Hoffmann and others. Ricker and Schwab

satisfactory explanation of their origin is that they arise from the pilosebaceous system, particularly from the epithelium of sebaceous glands.

DIAGNOSIS

The diagnosis of cylindroma is fairly easy. The onset is usually early in life and may follow trauma. The lesions become fully developed in later life (40 to 70). They grow and multiply slowly. Usually other members of the family are similarly afflicted, particularly the women. The general health is good and complaints are absent except for the unsightly appearance and foul-smelling secretion.

There are several conditions which may be confused with cylindroma:

1. Sebaceous cyst. These are usually solitary and are covered by pale or normal skin. They are spherical in shape and are not lobulated or pedunculated.

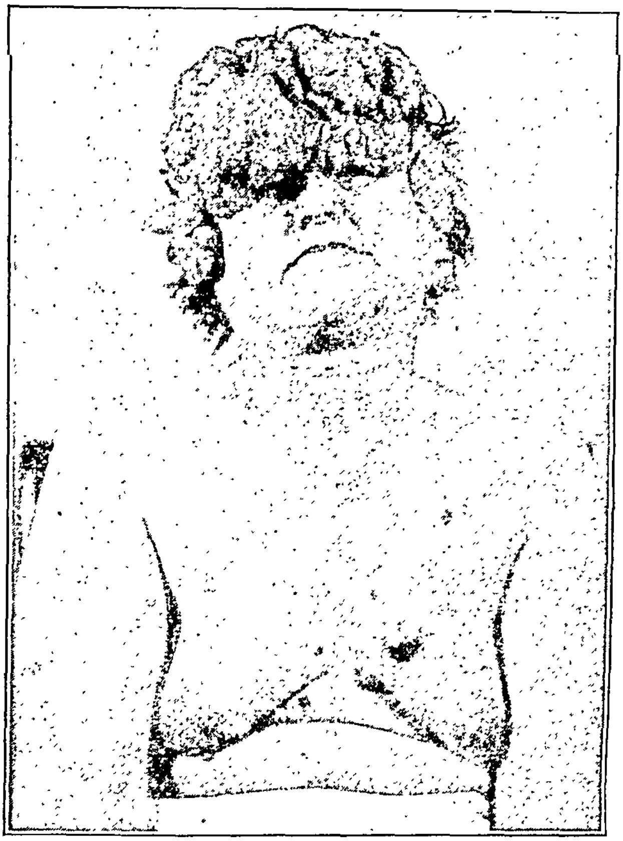

Fig. 3.—Anterior view showing extensive involvement of the scalp with solitary lesions on the breasts and the upper part of the abdomen. The large lesion overhanging the right eye and the smaller lesion on the left breast were removed for biopsy.

2. Endothelioma capitis. Biopsy will distinguish this disease from cylindroma.

3. Neurofibromatosus (von Recklinghausen's disease). The diagnostic feature of a neurofibroma is the fact that it may be invaginated through a ring in the skin but will spring back when released. There is only a 17 per cent hereditary factor in von Recklinghausen's disease, whereas almost all cases of cylindroma give a history of involvement of other members of the family.

TREATMENT

If they are not too extensive, the lesions may be removed by electrodesiccation or surgical excision. When there is extensive involvement, as in the patient described by Gabarro,[6] radical surgical removal followed by a plastic repair may be successfully employed. Roentgen rays are not of value against this disease.

REPORT OF CASE

The following case of cylindroma is reported because (1) it is believed to be the most extensive case ever reported in American medical literature, and (2) surgical intervention was refused.

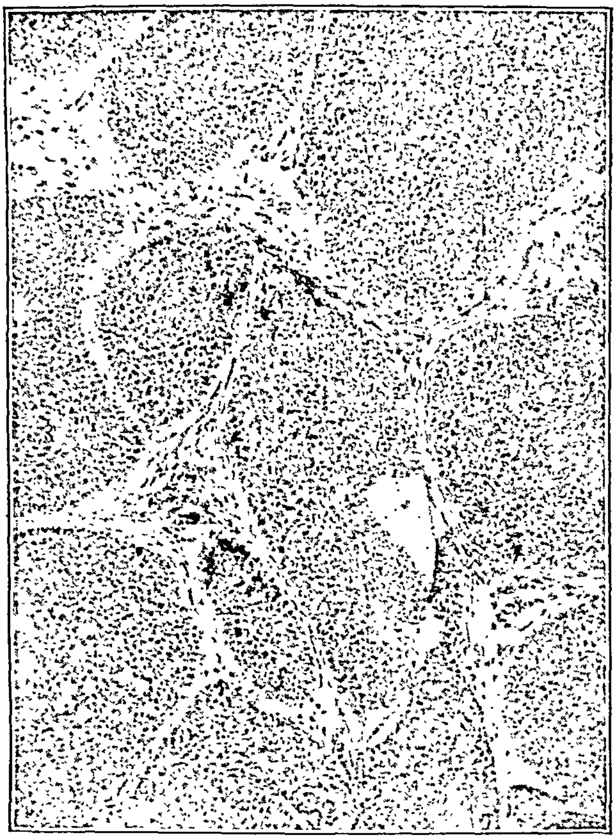

Fig. 4.—Low power magnification, slightly reduced. Note the rounded masses of epithelial cells separated by bands of hyalinized connective tissue.

Mrs. J. R., a white woman aged 47, was first seen in the outpatient dermatologic department of Hamot Hospital on Feb. 15, 1946. Her general health was good. She stated that following an injury to her scalp which occurred in early life she noticed "some small lumps" on her scalp. These continued to grow in size and number. Examination revealed a growth covering the entire scalp and extending down over the eyes and ears (fig. 3). The lesions were pinkish and bluish and varied from the size of a pea to that of a small orange. The largest lesion hung down over the right eye and interfered with the vision. The lesions were lobulated and pedunculated. Hair was present in moderate amount.

The gross appearance was that of a scalp covered with grapes and small tomatoes (fig. 1). Some of the lesions were firm and some were rubbery in consistency. There were also various sizes of solitary nodules on the face, neck, chest, abdomen and upper part of the back. There was a small group of closely set lesions on the lower portion of the back (fig. 2).

An unbearably foul odor due to a purulent secretion between the tumors emanated from the scalp. It was almost impossible to be near the patient.

She stated that her father and a sister, both of whom are deceased, had had similar but much less extensive, lesions of the scalp. A niece, the daughter of the sister mentioned, is similarly afflicted.

On Feb. 22, 1946 the patient was admitted to Hamot Hospital. Through the use of penicillin compresses (1 to 500) and penicillin by injection, the infection cleared up and the foul odor subsided somewhat. On March 13, 1946 two lesions were removed surgically by Dr. J. W. Switzer. One of these was the largest, which hung down over the right eye. During its removal, there was difficulty in controlling the bleeding. The other lesion which was removed had been located on the left side of the chest and was about the size of a walnut. Biopsies were performed by Dr. E. L. Armstrong.

It was suggested to the patient that mass removal of the tumor as performed by Gabarro[6] on his patient be permitted, but the patient's husband refused. It is of interest that she took great pride in her unusual appearance and enjoyed being the center of attraction when presented before various clinics.

She was discharged from the hospital on March 29, 1946.

BIOPSY

The biopsy report was as follows: The sections showed that the specimens were composed of varying sized rounded masses of epithelium derived from the basal layer. These epithelial masses were separated by bands of hyalinized connective tissue. The bands were varied in width. The cells were more or less uniform in size and were small, with deep-staining rounded nuclei. Mitotic figures could not be demonstrated in nuclei of basal cells (see figs. 4 and 5).

This description compares favorably with that given by McCarthy in "Histopathology of Skin Diseases" (page 358).

SUMMARY

1. This case of cylindroma is believed to be the most extensive one reported in American medical literature. The case is typical, however, in that it occurred in a woman who gave a history of involvement of other members of the family.

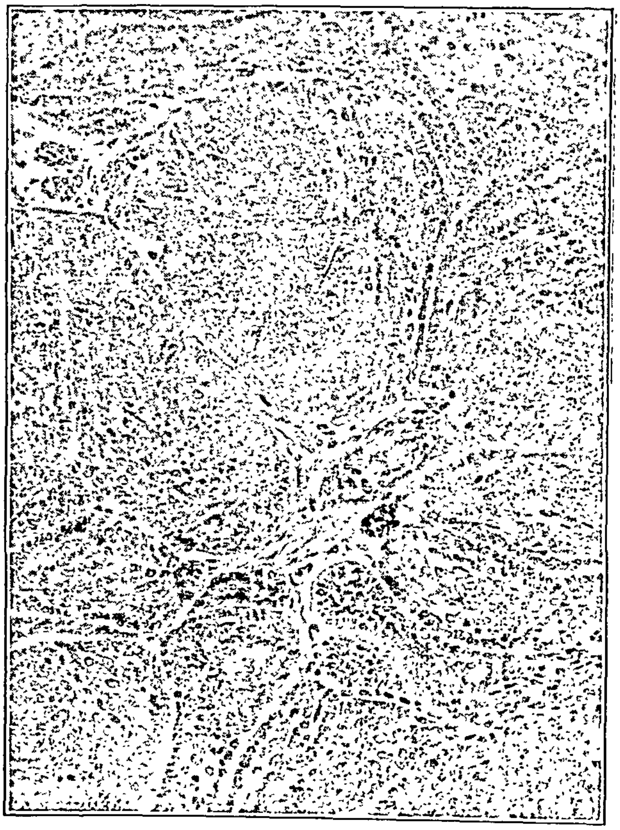

Fig. 5.—High power magnification, slightly reduced. Note the uniformity of size of the cells and the deep-staining rounded nuclei. Mitotic figures are absent.

2. Surgical intervention, except for the removal of a large mass which interfered with vision of the right eye and a small lesion from the left side of the chest for biopsy, was refused.

Special Article

OBSERVATIONS AT THE 1946 DOCTORS' ART SHOW

ROSE LAUGHLIN
Evansville, Ind.

The American Physicians Art Association, now almost ten years young, held their annual art show at San Francisco July 1 to 5, 1946. The city fathers made the beautiful War Memorial Civic Opera House available for the purpose. The entire mezzanine floor was used, so that over 5,000 square feet of hanging surface was available. This was a larger area than that of any previous exhibit.

On the first day, the front doors were kept locked until the official opening hour, noon. Yet for two hours before noon over 400 eager persons "beat the gun" by coming around to the back door, through the stage entrance. It was an impressive demonstration of art laughing at locksmiths.

The surgeons, gynecologists and obstetricians and the neurologists and psychiatrists of the American Medical Association held their scientific meetings on other floors of the Opera House while the art exhibit was taking place on the mezzanine.

An amusing incident occurred on the first day, before everybody attending the convention became oriented. A couple of young physicians still in army uniform walked up the stairs and spent half an hour in the art show before one of them suddenly remembered that he was due in room 302 where the N. P. (neurology and psychiatry) section was holding its scientific meeting. His companion seemed to enjoy his discomfiture. "Why Bill, you're in the N. P. right here. Look at these pictures. We try to get our patients to do occupational therapy like this, and here we are—you and I—not practicing what we preach."

He was expressing, in a breezy way, what hundreds of physicians have discovered and what was best expressed by that great scholar Sir William Osler when he said: "One cannot practice medicine alone, and practice it early and late, as so many of us have to do, and hope to escape the malign influences of a routine life. The incessant concentration of thought upon one subject, however interesting, tethers a man's mind in a narrow field. The physician needs a clear head and a kind heart; his work is arduous and complex, requiring the exercise of the very highest faculties of the mind, while constantly appealing to the emotions and finer feelings."

The proof of the doctor's need for art as a recreation, as a form of "work by the side of work," is to be found in the fact that over 300 of this year's art works were by physicians who had been "dabbling in art" less than three years; of these physicians 112 were at it less than one year!

The twenty-four judges were men and women on the firing line of the various art mediums who had been selected by Dr. Grace Morley, head of the San Francisco Museum of Art. They worked for hours, singly and in groups, returning several times when necessary, reviewing pieces under different lights, taking things down off the walls, putting some back, removing others, gathering them in small groups on the floor and arguing amongst themselves like lawyers over their respective merits.

The judges seemed to favor originality of conception more than execution. In some instances they were critical of the mixing of styles in one piece. They were more severe with the older (in experience) artists than with the newcomers.

General view of the 1946 exhibit of the American Physicians Art Association.

Average Size of the Hypophysial Fossa.—The hypophysial fossas of young adult soldier patients have been measured in order to establish a standard. The average size was found to be *anteroposterior 10.66 and depth 8.30 mm.* . . . By comparison the average measurement of the fossas of six pituitary adenomas was anteroposterior 23 and depth 17 mm.—Heublein, G. W.: Some Observations Concerning the Hypophysial Fossa, *Am. J. Roentgenol.* **56**:318 (Sept.) 1946.

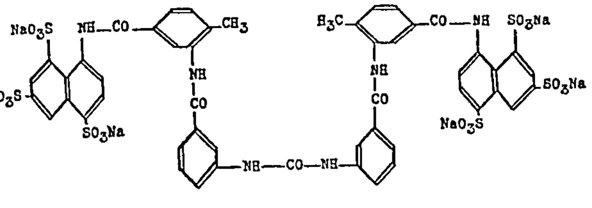
Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

NAPHURIDE SODIUM.—Suramin Sodium.—Hexasodium bis-(*m*-aminobenzoyl-*m*-amino-γ-methylbenzoyl-1-naphthylamino-4,6,8-trisulfonate) carbamide.—$C_{51}H_{34}O_{23}N_6S_6Na_6$.—M. W. 1429.18. The structural formula of naphuride sodium may be represented as follows:



Actions and Uses.—Naphuride sodium is a trypanosomicide which readily dissolves in sterile water; the solution is neutral in reaction, odorless and almost tasteless. Only freshly made solutions should be employed. It is slowly eliminated and remains active in the body for a considerable period, offering several months' protection against reinfection with the trypanosomes of both forms (Gambien and Rhodesian) of African sleeping sickness. It is claimed to produce excellent results in the first stage of trypanosomiasis and a favorable influence in the second stage of the disease. It is said to be of particular value in the prophylaxis of sleeping sickness. While the drug is relatively safe when properly used, it exerts an irritant action on the kidney; even after comparatively small doses there is frequent occurrence of albumin and sometimes hyaline and granular casts and red blood cells in the urine. However, albuminuria generally disappears spontaneously in about six weeks. The drug should be used only with great caution in patients with renal insufficiency and albuminuria, since severe nephritis, amblyopia, amaurosis and anuria have been noted. In larger doses naphuride sodium may have a hemolytic action. Occasionally dermatitis, chill, fever, headache, nausea and pruritus may be noticed, and more rarely conjunctivitis, stomatitis, cutaneous hemorrhages, globinuria and agranulocytosis. Since the compound is slowly eliminated and has a cumulative action, side effects may appear after cessation of treatment. The drug should not be continued in patients who show intolerance to initial doses. During treatment daily urinalysis and determination of blood pressure has been suggested, as have frequent complete blood counts, determination of nonprotein nitrogen content of the blood, and determination of the potassium, sodium and chloride content of the blood, so that degeneration of the adrenal cortex, if it occurs, may be detected early.

Dosage.—Naphuride sodium is usually administered intravenously in a freshly prepared 10 per cent solution. If a venipuncture is impossible, the solution may be injected intramuscularly. During the preparation of a solution, the powder is sprinkled to avoid formation of clumps on the surface of sterile distilled water. In the treatment of African sleeping sickness, the average single dose for adults is claimed to be 1 Gm. and the total dose from 5 to 10 Gm., 1 Gm. being given at weekly intervals. Some administer 1 Gm. on consecutive or on alternate days for three doses, followed by 1 Gm. weekly for from two to seven additional doses, so that the total dose is from 5 to 10 Gm. Combined treatment with naphuride sodium and tryparsamide has also been recommended, since cases with invasion of the central nervous system, as may occur early in the disease, are favorably influenced by the arsenical.

For the prophylaxis of African sleeping sickness the dose for adults is 1 Gm., for children from 0.3 to 0.75 Gm. and for infants from 0.15 to 0.2 Gm. The same dose is repeated in a week. At the expiration of three months, but not before, a similar prophylactic procedure may be followed.

Tests and Standards.—

Naphuride sodium occurs as a white to slightly pinkish, odorless, almost tasteless powder, which darkens on exposure to light. It is readily soluble in water; insoluble in acetone, benzene and ether. It is incompatible with strong acids or alkalis. The powder does not exhibit an exact melting point. An aqueous solution of naphuride sodium is slightly colored and is neutral to litmus (*p*H of a 10 per cent solution is about 6.0).

Place 1 cc. of 1 per cent solution of naphuride sodium in a test tube and add 2.5 cc. of *o*-phenanthroline ferrous complex solution (U. S. P. XII, p. 739): a red precipitate forms.

Naphuride sodium responds to tests for the presence of carbon, hydrogen, nitrogen, sulfur and sodium.

Dissolve about 0.5 Gm. of naphuride sodium in 20 cc. of water, add 5 cc. of hydrochloric acid; cool and then add 1 drop of tenth-normal sodium nitrite solution. Place a drop of the mixture on starch-iodide paper: a blue-black spot is produced *(absence of free amino groups).*

Fuse 1 Gm. of naphuride sodium with sodium hydroxide and add small portions of potassium nitrate until the melt is completely oxidized. After cooling, dissolve the residue in water, acidify with nitric acid and add 15 cc. of tenth-normal silver nitrate. Boil the mixture to expel the nitrite present, cool, filter to remove the silver chloride formed and titrate the excess of silver nitrate with tenth-normal ammonium thiocyanate solution, using ferric ammonium sulfate as the indicator: the amount of chloride found should not be more than 1 per cent.

Dry about 1 Gm. of naphuride sodium accurately weighed to constant weight at 150 C.: the loss in weight should not exceed 15.0 per cent.

Ash about 0.4 Gm. of naphuride sodium in the presence of sulfuric acid: the sulfated ash is not more than 30 per cent calculated to the dry substance.

Dissolve about 0.5 Gm. of naphuride sodium, accurately weighed, in 20 cc. of 10 per cent sodium hydroxide solution contained in a flask and heat under reflux for five hours. Cool, transfer the contents of the flask to a beaker and dilute to about 100 cc. Acidify the solution with 15 cc. of hydrochloride acid, cool to 0-10 C., add a few crystals of potassium bromide and titrate with tenth-normal sodium nitrite solution, using starch-iodide paste as the outside indicator. Each cubic centimeter of tenth-normal sodium nitrite is equivalent to 0.0238 Gm. of anhydrous naphuride: the amount of naphuride sodium found is not less than 97 per cent calculated to the dry basis.

Winthrop Chemical Co., Inc., New York
Naphuride Sodium: 1 Gm. ampuls.

THE Rh FACTOR: A CRITICAL APPRAISAL

The rapid application of the discovery of the Rh factor to the clinical problems of explanation and prevention of hemolytic intragroup transfusion reactions, as well as diagnosis and treatment of fetal erythroblastosis, has brought an avalanche of publications. Some of the conclusions seem to have been drawn hastily from limited observations. A large number of articles in magazines and in the daily press have been factually erroneous. The prevailing confusion is fraught with possible serious consequences. Some young couples have been advised not to have children for no other reason except that the husband was Rh positive and the wife Rh negative. In several instances the death of the first child of such couples was attributed to fetal erythroblastosis on the basis of the Rh factor determinations in the parents, while the necropsy revealed other causes of death. Cesarean sections have been advocated by some as a means of saving babies with erythroblastosis by eliminating the damage of the last few weeks of intrauterine life.

Much remains to be learned regarding the Rh factor, but the verified information thus far accumulated justifies certain conclusions with the reservation that they may have to be revised as our knowledge increases.

The evidence indicates that an Rh-negative wife of an Rh-positive man is almost certain to have at least one normal child unless she has received blood transfusions in the past. *Transfusions of Rh-positive blood* have been found in the history of an impressively large number of women whose first children had erythroblastosis. Only one in from twenty-five to fifty Rh-negative wives of Rh-positive husbands becomes sensitized to the Rh factor and gives birth to babies with erythroblastosis. The treatment of erythroblastosis with judiciously administered transfusions, preferably of Rh-negative blood, is saving a large proportion of infants who would have otherwise succumbed to the disease. One can nowadays be prepared for the approaching trouble by testing women for Rh antibodies during pregnancy. New types of antibodies have been discovered. To the previously known Rh agglutinins Race[1] and Wiener[2] have added an antibody which combines with the red cells without clumping them but which prevents the clumping of the red cells by a subsequently added agglutinating serum. Race calls it "incomplete" antibody, and Wiener named it "blocking antibody or blocker." Diamond[3] showed that agglutination by the serum of an Rh-negative person sensitized by Rh-positive blood may become manifest if a 50 per cent suspension of cells or preferably whole citrated blood is used when the usual technic employing a 2 per cent cell suspension has failed. Wiener[4] and Diamond[5] have shown that agglutination of Rh-positive red cells may be demonstrated in serum which fails to agglutinate in the usual test if serum or plasma or human or bovine albumin is used as a menstruum in place of isotonic solution of sodium chloride. Wiener uses the term "conglutinin" or "glutinin" for the substance responsible for the phenomenon. Coombs[6] suggested still another technic. He uses an antihuman globin serum produced in rabbits. A drop of it added to Rh-positive red cells clumps them though they failed to be agglutinated by the serum of a sensitized Rh-negative person. The *antiglobulin* serum produced in the rabbit reacts with the globulin of the Rh antibody, which covers the red cells with a fine film.

Probably these newly observed antibodies (incomplete, blockers and conglutinins) are all one and the same antibody to be distinguished from the regular agglutinins. The practical result thus far has been the possibility to detect Rh sensitization in almost 100 per cent of mothers of babies with erythroblastosis. Detection of sensitization during pregnancy means, as a rule, erythroblastosis in one of its forms in the infant except in cases in which antibodies have been left behind from a previous pregnancy. Therefore early testing and periodic follow-up during pregnancy are recommended. A sharp rise points to the presence of an Rh-positive fetus with likelihood of erythroblastosis, though cases have been reported of antibodies demonstrated during pregnancy followed by subsequent birth of healthy Rh-positive infants. This, however, is likely to be a rare exception.

It has been suggested that agglutinins in the serum of a pregnant woman have a different prognostic significance than the so-called blocking antibodies[7] in the sense that the former are more frequently followed by severe icterus and the latter by hydrops or severe anemia. The evidence indicates that while this may be true in a series of cases treated statistically there are too many exceptions to permit practical application to individual cases.

There is little to recommend cesarean section as a means of saving babies with erythroblastosis. Too many disappointments have been experienced. The handicap of prematurity is rarely outweighed by the alleged shortening of exposure to the damaging action of maternal Rh antibodies. The crux seems to be our inability thus far to recognize with certainty the severity of the disease in the baby by the examination of the mother's blood. Possibly further study and especially critical correlation of quantitative and qualitative antibody values with the condition of the infants at birth will teach us to formulate more reliable indications for early termination of pregnancy.

BCG IMMUNIZATION

The results of the use of the BCG vaccine in man are influenced by so many factors that accurate evaluation is still difficult. All reports agree that the vaccine properly prepared and used is harmless, as cases of tuberculosis caused by BCG vaccine have not been reported thus far. In some cases in which vaccinated children developed and died of tuberculosis, the bacilli from the pleural exudate, cerebrospinal fluid and lungs were of the human and not the bovine type. Holm[1] of Denmark states that since 1940 vaccination with the bacillus of Calmette-Guérin has been adopted in that country as an essential weapon in the fight against tuberculosis. A large part of the young people of Denmark are tuberculin negative. Since it is known that tuberculin negative persons acquire tuberculosis much more readily when exposed, BCG vaccination is believed to be a valuable adjunct in the control of tuberculosis. Extensive examinations for tuberculosis carried out in recent years utilizing identical technic (the Mantoux test), the same tuberculin dosage and even the same tuberculin dilutions have furnished a large amount of data on the extent of tuberculous infection in the Danish population. About two thirds of the population in Denmark at the age of 14 years gives a negative tuberculin reaction, and at the ages between 20 to 23 years one third of the population still gives a negative reaction. The vaccination renders by far the greater majority of vaccinated persons tuberculin positive. The duration of the reactivity is at least four years after the vaccination for the majority of the vaccinated persons. In Denmark BCG vaccination has been employed chiefly in tuberculous environments. All children with a negative reaction in a tuberculous environment have been vaccinated, also the newborn, and on development of a positive reaction they have been permitted to remain in their environment. This appears to be a severe test for the vaccination. However, the Tuberculosis Dispensary of Copenhagen reports that morbidity and mortality from tuberculosis among the children in a tuberculous environment have been reduced following vaccination to almost zero. Previously mortality among children exposed to tuberculosis in their homes was high, but in recent years children thus exposed have not died of tuberculosis, and children who become ill have a much milder form of tuberculosis than previously observed. Holm concludes that BCG vaccination gives considerable, although not absolute, protection. It protects almost completely against the morbid phenomena of the tuberculous primary infection, and it also affords considerable protection against genuine tuberculosis of the various organs, in particular against pulmonary tuberculosis.

Hertzberg[2] states that in Norway all children born in a tuberculous environment are vaccinated with BCG vaccine and an attempt is made to keep them isolated from the tuberculous members of the family until they become tuberculin positive. The allergy produced by the vaccination lasts more than three or four years. In the health department of Bergen, among 4,400 persons vaccinated who were observed up to three years only 1 developed ulcerative pulmonary tuberculosis and 11 developed tuberculosis of the hilar lymph nodes. The National Society Against Tuberculosis in Norway favored mass vaccination in 1945. Vaccination of persons living in a tuberculous environment, student nurses and others working in tuberculosis institutions, students in the graduating classes of the common schools, students and recruits seemed particularly desired.

Levine and Sackett,[3] reporting the results of BCG immunization in New York City, assume a more conservative attitude. Although most reports have been optimistic, they feel that the vast majority of these studies have been inadequately controlled. The Bureau of Laboratories of the New York City Department of Health undertook in 1926 a study of the efficacy of the BCG vaccine. The children vaccinated were referred from tuberculosis clinics and hospitals in New York City. They were all from tuberculous families and, with rare exceptions, were placed under observation before they were 12 months of age, many of them during the first four weeks of life. Children were not accepted for study after 1 month of age unless tuberculin tests up to 1.0 mg., roentgenograms and physical examinations were negative. In the first two years of the study the vaccine was given orally during the first ten days of life. By this method approximately 50 per cent developed positive tuberculin reactions. Thereafter the parenteral method of vaccination was used; it resulted in approximately 85 per cent of positive reactors. Up to Jan. 1, 1944, 2,084 children from tuberculous homes in New York City have been followed, of whom 1,011 were vaccinated and 1,073 held as controls. Up to 1933, 990 children were studied, 445 of whom were vaccinated. In this series the children were divided into two equal groups, those to be vaccinated and those serving as controls. A physician was assigned to a number of cases and was told to vaccinate half of the group. Subsequent experience has shown that by this method of selection the tendency was to inoculate the children of the more intelligent and cooperative parents and to keep the children of the noncooperative parents as controls. This was probably the source of considerable error, as the cooperative parents not only will take more careful precautions but will bring the child more regularly to the clinic for child care and feeding. In this series the tuberculosis mortality of the controls was over four times that of the vaccinated groups (3.38 per cent as against 0.68 per cent). In a second series the procedure of selection was changed in 1933 so that alternate children were routinely vaccinated, the remainder serving as controls. Mortality figures for the two groups in this series were essentially similar, the tuberculosis mortality of the vaccinated cases being 1.41 per cent as against 1.51 per cent for the controls. The authors point to a number of factors which could affect the comparative results, such as parental cooperation, economic conditions, racial distribution, exposure, lost cases and percentage of necropsies. Routine separation of children for three months before and three months after BCG vaccination to eliminate the hazard of continuous contamination with human bacilli was not found to be a feasible or safe procedure, although a small group where such separation was possible (91 vaccinated and 96 control cases) indicated that the BCG inoculation might be of protective value were such separation practical.

The efficacy of BCG vaccination must be judged by its ability to reduce the tuberculosis mortality of children vaccinated in their homes in the midst of a tuberculous environment. The authors conclude that as a public health measure the routine vaccination with BCG of children from tuberculous homes is less advantageous than removal of the tuberculous subject from the home.

THIAMINE UTILIZATION AND LIVE YEAST

Yeast has been regarded for many years as a substance supplying numerous valuable nutrients to the living organism. Modern studies by nutritionists have confirmed this general thesis but have shown that there is at least one exception, namely thiamine utilization when live bakers' yeast is included in the human dietary. Experimental studies have indicated[1] that thiamine utilization is poor when live bakers' yeast is included in the diet. This seeming paradox was first convincingly demonstrated in human subjects last year by a group of investigators at the University of Wisconsin.[2] These workers found, contrary to what might have been expected, that the incorporation of either of two types of live bakers' yeast (8 to 50 Gm., or approximately one to four cakes daily) in a normal human dietary resulted in an increased excretion of thiamine in the feces and a decrease in the urinary thiamine to subnormal levels. The use of a "high vitamin" type of bakers' yeast resulted in an even greater fecal loss of thiamine. Boiling the yeast preparation lessened the fecal loss, thus indicating that the impairment of thiamine absorption was due to the use of live yeast cells.

The observations mentioned were soon confirmed by studies on rats[3] in which the growth response was used as an index to thiamine utilization from live yeast and by other studies on normal human subjects.[4] The latter experiments indicated that only 17 per cent of the total thiamine present in the live yeast is available. The decreased absorption of thiamine from the gastrointestinal tract was attributed to thiamine removal and phosphorylation by the live yeast cell for its own metabolic purposes. Laxation is apparently not a decisive factor.[2] Current studies by the Wisconsin group[5] have further confirmed and extended the problem. Five young college women were fed a diet rich in thiamine to which for certain experimental periods live bakers' yeast (15 to 150 Gm. daily) was added. As before, the fecal loss of thiamine was definitely increased while the urinary thiamine level decreased to values "within the range accepted as denoting considerable to severe deficiency."

The practical implications of these scientific studies is obvious. Live bakers' yeast cannot longer be regarded as a satisfactory source of thiamine for human subjects; in fact the reverse is the case. Perhaps the comment should be added, however, that bakers' yeast cells killed

WINSTON-SALEM EMPLOYS TRANSCRIPTIONS EFFECTIVELY

An example shows how electrically transcribed programs such as those furnished by the American Medical Association can be promoted with great effectiveness by ingenious local cooperation. At Winston-Salem, N. C., the transcribed series "Before the Doctor Comes" was used with the cooperation of the city health department, the Forsyth Medical Society, the Bowman Gray School of Medicine and the Forsyth Health Committee with the Community Radio Council and Station WSJS. After the broadcasts had been planned, announcements were sent throughout the community on mimeographed dodgers, and publicity was arranged through local newspapers, daily and weekly, and other publications reaching various groups of people. The transcribed programs played ten minutes, leaving approximately three minutes for local participation. This was supplied by "live" broadcasts made by physicians and other community leaders, including the health officer and the health educator. Thus a fully rounded fifteen minute program was produced, and the local interest and usefulness of the transcriptions were enhanced by the supplementary material provided, which had a distinctly local flavor. Also it was possible to offer booklets and other material pertinent to the topic and thus encourage listeners to write in. The success of this program called forth a letter from the radio station expressing satisfaction with the results of the broadcasts and offering its full cooperation for future projects.

SKIN DISEASES AND VITAMIN A

Much effort has been devoted recently to studying the possible connection between certain skin diseases and the levels of vitamin A in the blood plasma. Two British investigators[1] determined the plasma vitamin A levels in 116 dermatologic patients and compared them with 116 control patients. A mean value of 116 international units of plasma was found in patients with skin disease, and this was virtually identical with the mean value of 113 international units found in the controls. Some support was found for the theory that secondary deficiency of vitamin A might be of some significance in a few rare skin diseases. In 6 cases of Darier's disease, 2 of pityriasis rubra pilaris and 3 of ichthyosis the mean level of vitamin A in the plasma was 77 international units. In patients with Darier's disease and pityriasis rubra pilaris the administration of large doses of vitamin A concentrate resulted in an eventual plasma vitamin A level considerably above normal values. In 2 of the patients with Darier's disease the skin became normal or nearly so after treatment with vitamin A and grenz rays. The other patients with Darier's disease showed less improvement, and in 1 the lesions remained unchanged even when the vitamin A levels in the plasma reached high levels. Two of the patients with pityriasis rubra pilaris showed some, but incomplete, improvement of the skin when the plasma vitamin A levels reached normal or higher than normal levels. It would seem from these and other studies that the relation between the amounts of vitamin A in the blood plasma and the appearance of the skin lesions in several rare dermatologic conditions might be of significance, though in the vast majority of skin diseases there is little or no direct relationship.

PROLONGED EXPOSURE TO SIMULATED HIGH ALTITUDES

Recently D'Angelo[1] reported studies on the respiratory metabolism of 6 healthy men subjected to prolonged exposure at simulated altitudes of 8,000 to 10,000 feet. The men were kept in the low pressure chamber for ten hours without supplementary oxygen and under standardized conditions and restricted food intake. The respiration was increased under the conditions of the study. This involved an increase in depth rather than in rate of breathing and was believed to indicate a respiratory alkalosis. The physiologic effects included an increase in the minute volume and carbon dioxide elimination, elevation of the respiratory quotient and a shifting of the urinary p_H toward alkalinity in all those who displayed appreciable hyperventilation. Furthermore, various behavior changes, notably somnolence, irritability, inattention, lack of volition and fatigue, were observed. D'Angelo suggests that serious consideration ought to be given toward putting a high altitude limit on prolonged flights without supplementary oxygen. He also suggests that the use of extra oxygen at altitudes as low as 8,000 feet may be advisable. The curious feature of this study is the comparatively low altitude at which supplementary oxygen would seem to be indicated. Many people live permanently at altitudes of close to 8,000 feet (and even above) without apparent harmful mental or physiologic effects. Consequently a number of pertinent questions arise. Are permanent residents of high altitude areas affected more than has so far been realized? Does the speed of rise to 8,000 or 10,000 feet as employed in D'Angelo's studies influence the effects of the high altitude more than would a more gradual rise and lengthy acclimatization? Although remaining at 8,000 to 10,000 feet for ten hours is called "prolonged" by D'Angelo, is it likely that the exposure is too short in which to bring about the physiologic adjustments which can be obtained by longer exposures? These and other readily propounded questions serve to illustrate the deficiencies still remaining concerning knowledge of the effects of altitude on the human body.

ORGANIZATION SECTION

Official Notes

RESOLUTIONS TO BE PRESENTED TO HOUSE OF DELEGATES

NOTE.—These resolutions are published in accordance with a request of the House of Delegates to the effect that resolutions to be presented before the House of Delegates be published thirty days before the House of Delegates is to convene in session

The following resolutions will be submitted by the delegates of the Colorado State Medical Society:

Resolution on Prohibition of Political Activity on Part of the United States Public Health Service

WHEREAS, The United States Public Health Service was created, organized and is amply financed for certain specific purposes, namely the promotion of the public health, the prevention of disease, the control of epidemics and the extension of help and advice to state and local communities in these and similar problems of disease prevention, and

WHEREAS, The United States Public Health Service in wartime has certain additional duties and functions related to the armed forces in assisting them in protection of the nation and its citizens, and

WHEREAS, Existing federal laws contemplate that regular officers of the United States Public Health Service shall devote their full time to the aforementioned duties, and

WHEREAS, Certain officers and members of the United States Public Health Service, including its Surgeon General, have within the last year so put aside consideration of the functions and duties for which they were appointed and commissioned as to devote much of their time and energy to political activities, even to the extent that the Surgeon General of that service has issued written orders to his staff and his officers directing their utterances and thinking on highly controversial questions of medical legislation wholly unrelated to the proper functions of the United States Public Health Service and in opposition to American democratic processes, now therefore be it

Resolved, That the House of Delegates of the American Medical Association condemns without qualification, as a perversion of function and dereliction of duty, political and partisan activities on the part of officers of the United States Public Health Service, including its Surgeon General, and recommends that steps be taken to prohibit political activity on the part of the United States Public Health Service, and that further steps be taken to restore the prestige of this important department of our government in the scientific field for which it was created, organized and financed

Resolution on Change of Policy of American Specialty Boards

WHEREAS, Certain of the American specialty boards have recently announced discontinuance of their former practice of according credit for preceptorships with a certified diplomate and have ruled instead that every applicant for certification must serve a lengthy residency following his internship; and

WHEREAS, This recent change in policy constitutes an unfair imposition on many returned medical veterans and other young physicians who find it impossible to obtain such residencies, and

WHEREAS, It is the opinion of the American Medical Association that the preceptorship is one of the best methods of teaching the art of medicine, and

WHEREAS, Qualified and experienced preceptors already certified by these boards are available in all parts of the United States, and

WHEREAS, The art of medicine is frequently neglected in hospital residencies owing to overemphasis on the science of medicine, now therefore be it

Resolved, That the House of Delegates of the American Medical Association requests the Advisory Board for Medical Specialties and the several American specialty boards to review and reconsider their policies in relation to residencies and preceptorships in accordance with the foregoing statements

Resolution on Appointment of Reference Committees

WHEREAS, The By Laws of the American Medical Association contemplate the appointment of House of Delegates' reference committees from the membership of the House of Delegates; and

WHEREAS, The duty of reference committees to pass judgment on the activities of elected and appointed officers makes it obviously improper for these committees to be composed of the persons whose actions they are expected to judge, and

WHEREAS, In recent years the Board of Trustees of the American Medical Association has acted as a reference committee of the American Medical Association House of Delegates to pass judgment for the House of Delegates on actions previously taken by the Board of Trustees; and

WHEREAS, Official protest of this action has been received from the Colorado State Medical Society, now therefore be it

Resolved, That the House of Delegates of the American Medical Association instruct its speaker to utilize as reference committees of this House of Delegates only committees composed exclusively of elected Delegates.

THE ATLANTIC CITY SESSION

Representatives of Various Sections to the Scientific Exhibit

Representatives to the Scientific Exhibit have been appointed by each section of the Scientific Assembly to assist and advise in securing exhibits for the Atlantic City session, June 9-13, 1947. Their names and addresses follow:

Internal Medicine—Dr Thomas C. Garrett, 3803 Oak Road, Germantown, Philadelphia

Surgery, General and Abdominal—Dr Warren H. Cole, University of Illinois College of Medicine, 1853 West Polk Street, Chicago 12.

Obstetrics and Gynecology—Dr. Frederick H. Falls, University of Illinois College of Medicine, 1853 West Polk Street, Chicago 12.

Ophthalmology—Committee on Scientific Exhibit, Dr. Georgiana D. Theobald, 120 Medical Arts Building, Oak Park, Ill, chairman; Dr. Derrick Vail, 55 East Washington Street, Chicago 2, and Dr. A. B. Reese, 73 East Seventy-First Street, New York 21.

Laryngology, Otology and Rhinology—Dr. Paul H. Holinger, 700 North Michigan Avenue, Chicago 11.

Pediatrics—Dr Albert V. Stoesser, 412 Delaware Street S E., Minneapolis

Experimental Medicine and Therapeutics—Dr. Robert W. Wilkins, Evans Memorial Hospital, 65 East Newton Street, Boston.

Pathology and Physiology—Dr. F. W. Konzelmann, Atlantic City Hospital, Atlantic City, N. J

Nervous and Mental Diseases—Dr. A. B. Baker, University of Minnesota Medical School, Minneapolis

Dermatology and Syphilology—Dr. Francis W. Lynch, 350 St. Peter Street, St Paul.

Preventive and Industrial Medicine and Public Health—Dr. Paul A. Davis, 1436 Delia Avenue, Akron 2, Ohio

Urology—R. John H. Morrissey, 40 East Sixty First Street, New York.

Orthopedic Surgery—Dr. David M. Bosworth, 742 Park Avenue, New York 21.

Gastro Enterology and Proctology—Dr. Donovan C. Browne, 1534 Aline Street, New Orleans

Radiology—Dr. S. W. Donaldson, 326 North Ingalls Street, Ann Arbor, Mich

Anesthesiology—Dr. Urban H. Eversole, 605 Commonwealth Avenue, Boston

General Practice of Medicine—Dr. J. Craig Bowman, 208 South Sandusky Avenue, Upper Sandusky, Ohio

Application blanks for space may be obtained from any of the section representatives or from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago 10

Council on Medical Service

PREPAYMENT MEDICAL CARE PLANS

The Hospitalization and Health Center Program

The medical profession together with hospital and farm organizations worked for the enactment of this legislation. Announcement was made in THE JOURNAL, September 21, page 155, in regard to the formation of the Federal Hospital Council and the Advisory Committee "to assist Surgeon General Thomas Parran of the U S. Public Health Service in the administration of the hospital survey and construction act" It has been pointed out that the membership of the Federal Hospital Council, composed of eight persons, does not include a farm representative or an official representative from the American Medical Association or the American Hospital Association. One physician, Dr. Robert C. Buerki, dean of the Graduate School of Medicine, University of Pennsylvania, is on the Council Of special interest to the medical profession is the fact that Michael Davis is a member of this council as a representative of "the consumers of medical service."

THE ADVISORY COMMITTEE

The American Medical Association is represented on the Advisory Committee by Dr. Franklin S. Crockett, chairman, Committee on Rural Medical Service of the American Medical Association, of Lafayette, Ind, and Dr. Victor Johnson, secretary, Council on Medical Education and Hospitals, of the American Medical Association

The Advisory Committee composed of some twenty four men, should not be mere window dressing. From the reports of the first meetings of this group held September 17 and 18 in Washington it is evident that the committee will play an important part in any plans and program which are set up by the Surgeon General and the Federal Hospital Council.

RESPONSIBILITY OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association through its Board of Trustees, the Councils on Medical Service and Medical Education and Hospitals and the Bureau of Legal Medicine and Legislation will keep in touch with developments that occur. Some work should be done promptly to set forth the conditions under which the medical profession may best cooperate in the implementation of the provisions of the Hill Burton bill. The Council on Medical Service and the Council on Medical Education and Hospitals have been asked by the Board of Trustees to draw up minimal standards for state societies to utilize in assisting in carrying out the provisions of the Hill Burton bill.

"Make no mistake the local people must watch every factor to see that those administering the program at the national state and local levels do not take control of the situation and thereby defeat the purpose of Congress and the Hill Burton legislation" says Ransom E Aldrich chairman American Medical Care Committee, Farm Bureau Federation Jackson Miss.

PREPAYMENT

The "Seal of Acceptance"—To date twenty-seven voluntary prepayment medical care plans have been awarded the Council's "Seal of Acceptance." They are

California Physicians' Service, San Francisco
Iowa Medical Service, Des Moines
Michigan Medical Service Detroit
Surgical Care, Inc, Kansas City, Mo
Nebraska Medical Service, Omaha
Medical Surgical Plan of New Jersey Newark
Ohio Medical Indemnity, Inc, Columbus
Medical Service Association of Pennsylvania *Harrisburg*
Oregon Physicians Service Salem
Physicians Association of Clackamas County Oregon City Ore
Hospital Service Corporation Birmingham Ala
Florida Medical Service Corporation Jacksonville Fla
North Idaho Medical Service Bureau, Lewiston Idaho
Genesee Valley Medical Care, Rochester, N Y
Hospital Saving Association of North Carolina, Chapel Hill
Oklahoma Physicians Service, Tulsa
Coos Bay Hospital Association Coos Bay Ore
Pacific Hospital Association, Eugene Ore
Klamath Medical Service Bureau, Klamath Falls Ore
Group Medical and Surgical Service Dallas Texas
The Dallas County Medical Plan, Dallas Texas
Surgical Care Inc, Roanoke, Va
Medical Surgical Service, Inc, Clarksburg W Va
Marion County Medical Service, Inc Fairmont W Va
Medical Surgical Care, Inc, Parkersburg W Va
West Virginia Medical Service Wheeling
Hospital Service of California Oakland

Other applications have been received and will be acted on at the next meeting of the Council.

Eighty-Four Plans—Up to the present time the Council has found eighty four voluntary prepayment medical care plans in operation. Each of these offers a free choice of physician and is sponsored by either the medical profession the Blue Cross or both. These plans are spread over thirty-two states the territory of Hawaii and Puerto Rico. In addition some thirteen states and the District of Columbia are in various stages of plan development. Only three states are without a plan or program.

Three and One-Half to Four Million—Enrolment reports from most plans show general and encouraging growth for the first six months of this year. The total enrolment as of June 30, with a half dozen plans yet to report their figures, was 3 435 885. Six plans showed an increase of over 100 per cent and sixteen an increase of over 50 per cent. Many plans reporting each month have shown a constant increase in enrolment since June 30.

District of Columbia—"Medical Service of the District of Columbia" has been completed to offer a prepayment plan in the Capital. Twenty incorporators have been selected. The plan will be a "service plan" for single persons earning $2,500 and for families with a $4,500 income per year. The scheduled monthly dues are 75 cents for the individual, $1 50 for a man and wife and $1 75 for a family.

Montana Physicians Service—One of the increasing number of new plans to commence operation has announced that enrolment started as of August 1. Over 70 per cent of the members of the Montana Medical Association are participating physicians. In the first two months over 5 000 subscribers have joined the plan. Congratulations Montana!

Illinois Prepayment Program—The Illinois State Medical Society has struggled hard and long to evolve a prepayment medical care plan. The house of delegates approved a plan several months ago but several amendments adopted at the last minute have held up progress. A recent communication from Dr Harold Camp, society secretary, indicates that the serious difficulties have been ironed out. A special meeting of the house of delegates has given the go ahead signal.

Maryland—A joint committee of the Chirurgical Faculty and Associated Hospital Service of Baltimore drafted a program in May. The program called for a separate corporation to be administered by Associated Hospital Service. No further developments have been reported to the Council.

Idaho—The North Idaho Medical Service Bureau of Lewiston Idaho has been formed to provide a prepayment program for the northern part of the state. As of June 30 the enrolment was 2 227. The State Committee on Prepaid Medical Care has recommended that a statewide plan be deferred for the present, awaiting the experience in northern Idaho.

South Carolina—South Carolina one of the few states without a prepayment plan may have something started next spring. Mr Meadors, director of public relations, suggested in the May issue of the *South Carolina Medical Association Journal* that enabling legislation be proposed at the January 1947 session of the South Carolina general assembly.

Maine—The house of delegates of the Maine Medical Association has authorized the Committee on Prepaid Medical Care Plans to take the necessary steps to secure an enabling act "which would empower the Maine Medical Association to adopt a representative insurance plan when such can be formulated."

Rural Enrolment—Surgical Care Inc, of Kansas City Mo, reports very encouraging activities in rural enrolment. The plan started a rural enrolment program in the late fall of 1945 and by August of this year had 3 500 subscribers in the service. Enrolment has proceeded through the Missouri Farm Federation and community groups.

Prepayment Plan Not Insurance—The California State Supreme Court has ruled that the state insurance commissioner has no jurisdiction over California Physicians' Service. This ruling ends some seven years of litigation and indicates that California Physicians' Service is not an insurance plan within the meaning of the California laws.

Tennessee—The prepayment committee in Tennessee has been requested by the house of delegates to proceed with drawing up a complete service plan outline including constitution, by-laws and proposed contracts. At the same time the committee is to study the facilities of private insurance carriers and their willingness to underwrite a plan.

Wyoming—An interesting article in the *Rocky Mountain Medical Journal* reveals that the Public Policy and Legislative Committee of the Wyoming State Medical Society has discussed plans for the inauguration of a Prepayment Medical Plan for Wyoming. Some desire has been expressed to determine the advisability of associating any developed plan with Wyoming Hospital Service and combining under one administrative agency both medical and hospital coverage. Also considered was the advisability of combining any resulting organization with Colorado Medical Service. No further developments have been reported.

Minnesota—The Minnesota subcommittee working on contracts and rates met October 6 in St Paul. Two types of contracts are being considered at this time. One contract will cover surgical and obstetric procedures, while the other will include surgical and obstetric procedure with certain medical benefits added. It is reported that 75 per cent of the recommended starting capital of $100,000 has already been obtained.

Arkansas.—The Prepayment Committee for the State of Arkansas has been discussing the best means of developing a prepayment plan. At the latest report a definite decision had not been reached as to whether to develop a service plan to be underwritten by the doctors or to have the plan handled through private insurance.

Connecticut.—The *Connecticut State Medical Journal* reported in June that negotiations with a private insurance company had been discarded in favor of a plan to be promoted and sold by the Blue Cross Hospital Plan. Recent reports, however, seem to indicate that this original decision may be altered in favor of a private insurance underwritten program.

Arizona.—The house of delegates of the Arizona State Medical Association approved a medical service plan for the people of the state of Arizona. The plan provides for surgical and obstetric care for group insured hospital patients. It also provides care for fractures both in and out of the hospital. The service covers the employee and his family and unmarried dependents under 19 years of age.

Ohio.—Ohio Medical Indemnity, which began operations in January of this year, reports that on August 1 its enrolment was 39,459.

Health Service Association, Detroit.—The organization of a new corporation, Health Service Association, has been granted a preliminary certificate by the Commissioner of Insurance for the State of Michigan, according to recent reports. It has been indicated that this action was necessitated as a result of disagreements with certain policies of Michigan Hospital Service. These policies have resulted in several hospitals operated by the Catholic Sisters of Mercy to withdraw from participation in Michigan's Blue Cross Plan. This withdrawal has left certain Michigan cities without any hospital participating with the statewide program.

The incorporators of the new association (actively identified with Michigan Medical Service, the statewide medical care plan sponsored by the state medical society) are reported to feel this action necessary to enable Michigan Medical Service to offer a more complete health protection service in areas not serviced by Blue Cross.

Four Plans Over 200,000.—The four leaders in number enrolled as of June 30 are Michigan Medical Service, 847,881; California Physicians' Service, over 337,000; Massachusetts Medical Service, 275,000, and United Medical Service, 274,861. The average increase in enrolment for plans in the 200,000 to 500,000 group was 55 per cent.

Eleven Plans Between 50,000 and 200,000.—There are eleven plans showing June 30 enrolment between 50,000 and 200,000. In order of size these are Hospital Saving Association of North Carolina; Colorado Medical Service; Surgical Care, Inc., Kansas City, Mo.; Hospital Service of California; Group Hospital Service of Delaware; Western New York Medical Plan, Inc.; Hospital Care Association, Inc., North Carolina; Medical-Surgical Plan of New Jersey; Medical-Surgical Care, New York; Oregon Physicians Service, and Medical Service Association, Inc., North Carolina.

Increase in Enrolment of 362 per Cent.—The largest percentage increase in enrolment for the first six months of this year was 362 per cent. This fine increase was experienced by Oklahoma Physicians Service of Tulsa.

Regional Meetings with Plan Executives.—Executives of the various plans were recently canvassed to secure their reaction to a series of regional meetings. In this way it was thought that the Council staff could become better acquainted with the plan managers and their problems. This would be accomplished with a minimum of inconvenience to the busy executives. As far as expediency will permit, such meetings will be coordinated with other scheduled meetings in given areas. To date the plan executives are overwhelmingly in favor of the idea, with only a few plans not yet expressing their opinions.

Associated Medical Care Plans.—The auditorium in the American Medical Association headquarters was lent to A. M. C. P. for its first annual meeting held in Chicago on October 4 and 5. Dr. L. Howard Schriver, Cincinnati, was elected as the new president, and the remaining officers were reelected. They are William Bowman, C.P.S., vice president; Dr. Norman Scott, Newark, N. D., treasurer, and Jay C. Ketchum, Detroit, secretary.

Any medical care plan organization which meets and complies with the minimum standards for medical care plans approved by the Council on Medical Service of the American Medical Association shall, on approval of its application by the Commission (A. M. C. P.) be a full member.

It has been reported to the Council that fourteen plans have been admitted to full membership, with two plans admitted as associate members.

First Joint Conference of Insurance-Medical Committees.—Some time ago the Board of Trustees of the American Medical Association authorized a committee to meet with representatives of leading insurance associations. On September 18 representatives of the leading insurance associations of the United States met with the A. M. A. committee with a view of combining efforts toward solution of common problems.

As a result of the conference two committees were appointed, a committee on cooperation and a committee on rural enrolment. The purpose of the first is to further the close cooperation among all voluntary facilities for rendering health protection, and the second committee is to study the best means of affording protection offered by the combined voluntary facilities to those in rural areas.

It is hoped that much will be accomplished as a result of this conference and the work of the two committees.

STATE AND COUNTY MEDICAL SOCIETY ACTIVITIES

Virginia.—A recently published (July 1946) pamphlet of the Virginia Council on Health and Medical Care should be of interest to all state medical societies. It outlines the purposes, plans and program to date. For copies write to Miss Ellen H. Smith, 4050 Forest Hill Avenue, Richmond, Va.

New York.—If any of the state society officers are interested in material on antivivisection it might be well to get in touch with the New York Academy of Medicine or the New York State Medical Society. The medical profession in New York State has gone through a long legislative campaign on this subject and has prepared a number of excellent articles showing the need of animal experimentation.

Massachusetts.—Lowell has instituted a program of public education via advertising. This may be a new avenue to accomplish an important purpose.

Indiana.—Lake County Medical Society has entered into a new public educational project. It is a health bulletin, to be issued monthly, entitled "The Ounce of Prevention." A cooperated effort of private health agencies and the medical society, the bulletin will go to some 4,000 teachers, public health workers and industrial officials. Eventually it is hoped that distribution can be made to the 68,000 students in Lake County schools. The National Foundation of Infantile Paralysis, the Tuberculosis Association and the American Cancer Society each contributed $1,000 to the project.

Oklahoma.—Dick Graham of Oklahoma has a new associate in his capacity as executive secretary of the Oklahoma State Medical Association. He is Clayton Fondren, graduate of the University of Oklahoma and recently returned from four years with the Army Air Forces.

North Dakota.—Another newcomer to the lay secretary field is E. F. Engebretson, executive secretary of the North Dakota State Medical Association.

Massachusetts.—The Council of Massachusetts has voted to employ a director of medical information and education. It will be a full time position, probably similar to that of the executive secretary in other state societies.

Tennessee.—The Tennessee State Medical Association, in cooperation with the local medical societies, has been carrying on a series of health broadcasts. The programs are by electrical transcription, many of which are available through the A. M. A. Bureau of Health Education. They are fifteen minute programs and cover a wide variety of subjects.

Washington Letter

(From a Special Correspondent)

Nov 4, 1946

Appointment of Atomic Energy Commisson Presages Establishment of Medical Atomic Laboratory

Following appointment of the five man Atomic Energy Commission, of which David Lilienthal is the head, Dr Edward U Condon and Dr R E Dyer, directors respectively of the U S Bureau of Standards and the National Health Institute, said they will present preliminary plans to the commission for construction of a 10 to 20 million dollar atomic laboratory in Bethesda Md It will be virtually built around several tons of uranium At least two basic lines of research will be followed The Bureau of Standards will investigate measurement of and standardization of atomic materials The National Institute of Health will work alongside the bureau, investigating radioactive isotopes of various drugs and medicines, particularly in diagnosis and treatment of cancer The National Institute of Health will also study safety precautions for workers in atomic laboratories Plans will permit the use of the atomic laboratory by other scientific bodies in the area Dr Condon said the uranium pile would be a source of neutrons, atomic particles, for the production of radioactive materials for study

Dr. Muller Learns of Nobel Prize Award at Carnegie Foundation Conference

A telephone call from Sweden informed Dr Hermann Joseph Muller, professor of zoology at Indiana University, during a conference of the Carnegie Foundation here that he had been awarded the Nobel prize for medicine and physiology The award was for his work on heredity, through his discovery that mutations in the genes of living things can be changed through exposure to x rays Dr Muller studied at Columbia University under the late Dr Thomas Hunt Morgan, who won the prize in 1933 for his work in hereditary science Dr Muller is one of three scientists named to carry on a six year research program in genetics at Indiana University, for which the Rockefeller Foundation made a grant of $95,000 Last week the American Cancer Society made a grant of $4,500 to Dr Muller to finance his work

Socialized Medicine an Issue in Election Campaign

Coincident with the windup of the Congressional election campaign on November 5, socialized medicine became an issue in Maryland politics, with the Republican candidate for the Senate, Brig Gen John D Markey having asked Democratic Governor O Conor to state his position on state medicine The G O P nominee in a statement challenged "Where does he stand on this important question, the attempt to socialize medicine? This state, the home of the greatest physicians, is vitally interested Is Mr O Conor for or against? I am unequivocally against The electorate is entitled to know where Mr O Conor stands, and he ought to speak up before November 5"

Dr Walter A Bloedorn Elected President of the Association of American Medical Colleges

Dr Walter A Bloedorn dean of the George Washington Medical School, is the first Washington physician to be elected president of the Association of American Medical Colleges which held its fifty seventh annual meeting recently in Edgewater Park, Miss He was also named association delegate to the national commission of the U S Educational, Scientific and Cultural Organization

Scientists Plan to Visit Russia to Study KR Cancer "Cure"

A group of scientists from the National Cancer Institute and other cancer specialists may visit Moscow soon to study reports that a Russian preparation known as KR dissolves cancer in human beings without injuring the patient Dr V V Parin secretary general of the Soviet Academy of Medical Sciences revealed to a conference at the U S Public Health Service that a drug developed by Dr Gregory Roskin and his wife Dr Nina Kleuva, from dead germs of Chagas disease (American trypanosomiasis) had produced 'good results' in the treatment of cancer Dr Parin, who came here at the invitation of Surg Gen Thomas Parran of the U S Public Health Service warned that this did not mean that "the problem of cancer is solved" He said that at least five years must elapse before a cancer patient is cured Fifteen Russian human "guinea pigs" were reported to have been "clinically cured" through use of the drug

Dr Parin, who is also professor of physiology at the Third Moscow Medical Institute and is in this country to inspect governmental and private research centers, spiked rumors that had been circulated that Russian medical scientists during the war transplanted limbs from cadavers to maimed persons "Corneal transplants, yes, arms and legs, no" he said Occasionally blood had been taken from corpses for transfusion, but only rarely, as it was much more practical to use living dônors In Washington he visited the National Institute of Health, National Cancer Institute, Naval Medical Research Institute and other research laboratories

Weather Bureau to Give "Storm Warnings for Hay Fever and Asthma Sufferers"

Dr W C Jacobs, Weather Bureau climatologist, reports that the agency is planning to set up a "storm warning system for hay fever and asthma sufferers' by which it will forecast twenty-four to forty eight hours in advance the arrival of an air mass laden with ragweed pollen in a given area The region having the greatest ragweed pollen intensity is southern Indiana Air currents carry the pollen hundreds and even thousands of miles, and the climatologists plan to follow these pollen concentrations and map their courses

Two Doctors Honored for Ninety-Seven Years of Service to Children

For their combined total of ninety seven-years of service to young patients at Children s Hospital here Dr Joseph S Wall, chairman, and Dr Edgar P Copeland, vice chairman, of the institution s medical staff, were honor guests at a "family party" at the hospital They joined the staff as students, Dr Wall in 1896 and Dr Copeland in 1899

Coming Medical Meetings

American Medical Association House of Delegates Supplemental Session, Chicago, Dec 9 11 Dr George F Lull, 535 N Dearborn St, Chicago 10, Secretary

Conference of State Secretaries and Editors, Chicago, Dec 7 8 Dr George F Lull 535 N Dearborn St Chicago 10, Secretary

American Academy of Allergy, New York, Nov 25 27. Dr Karl D Figley, 316 Michigan St, Toledo 2, Ohio, Secretary.

American Academy of Dermatology and Syphilology Cleveland, Dec 7 12 Dr Earl D Osborne, 471 Delaware Ave, Buffalo N Y, Secretary

American Academy of Pediatrics, Pittsburgh Nov 13 16 Dr C G Grulee 636 Church St, Evanston, Ill, Secretary.

American College of Surgeons Cleveland Dec 16 20 Dr Dallas B Phemister, 40 E Erie St, Chicago 11, Secretary

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Nov 14 Dr Norman N. Smith 291 Whitney Ave, New Haven 1, Conn, Secretary.

American Public Health Association, Cleveland, Nov 12 14 Dr. R M Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Society of Anesthesiologists, New York, Dec 12 Dr Curtiss B Hickcox, 745 Fifth Ave, Room 1503, New York, Secretary

National Society for the Prevention of Blindness, New York, Nov 25 27 Mrs Eleanor Brown Merrill, 1790 Broadway, New York 19, Executive Director

North Central Medical Conference St Paul Nov 10 Mr R R Rosell, 493 Lowry Medical Arts Building, St Paul, Secretary

Post Graduate Medical Assembly of South Texas, Houston, Dec 3 5 Dr M B Stokes, 229 Medical Arts Bldg, Houston, Secretary

Puerto Rico Medical Association of, Santurce, Dec 13 15 Dr Rafael A Vilar, P O Box 3866 Santurce, Secretary

Radiological Society of North America Chicago, Dec 1 6 Dr Donald S Childs, 607 Medical Arts Bldg, Syracuse 2, N Y, Secretary.

Society of Surgeons of New Jersey, Newark, Nov 20 Dr Walter B Mount, 21 Plymouth St, Montclair, Secretary

Southern Surgical Association, Hot Springs, Va, Dec 10 12 Dr Alfred Blalock Johns Hopkins Hospital, Baltimore 5, Secretary

Western Surgical Association, Memphis, Tenn, Dec 5 7. Dr Warren H Cole 1853 W Polk St, Chicago 12, Secretary.

GOVERNMENT SERVICES

ARMY

ARMY AWARDS AND COMMENDATIONS

Colonel Samuel D. Avery

The War Department recently awarded the Legion of Merit to Col. Samuel D. Avery, M. C., U. S. Army, for his services from September 1939 to June 1946. During this time, says the citation, "the production of prophylactic vaccines and other products under his supervision increased to thirty times that of 1939. He maintained the effectiveness of typhoid vaccine to such a high degree that the incidence of typhoid and paratyphoid fevers in World War II was less than one-tenth that of World War I. Through his noteworthy efforts toward the prevention from the typhoid fevers, Colonel Avery made a major contribution to the war effort." Dr. Avery, a graduate of Rush Medical College, entered the service April 25, 1941

Lieutenant Colonel Herbert S. Ripley

The War Department recently announced the award of the Bronze Star Medal to Lieut. Col. Herbert S. Ripley, M. C., O R. C., Oak Park, Ill., for meritorious achievement in Biak, Netherlands East Indies, from Oct. 15, 1944 to Aug. 1, 1945 "in connection with military operations against the enemy. As chief of the neuropsychiatric section of a large general hospital," says the citation, "Lieutenant Colonel Ripley was responsible for the planning and organization of complete facilities for the care and treatment of psychotic cases. Despite difficult working conditions and acute shortage of experienced personnel, he succeeded through unselfish and diligent labor in providing an efficient service during a period in which large numbers of patients were being received from the Philippine Island campaigns. He devoted additional time to the instruction and training of other medical officers and supervised the establishment and operation of a convalescent and rehabilitation section which received high praise from medical authorities. As a result, many patients who ordinarily would have been evacuated to the United States were rehabilitated and returned to duty in the theater. By his superior professional ability, resourcefulness and devotion to duty Lieutenant Colonel Ripley made a distinguished contribution to the care of battle casualties in the Southwest Pacific area." Dr. Ripley, a graduate of Harvard Medical School, entered the service July 15, 1942.

Major John B. Bennett

The War Department recently awarded the Bronze Star Medal to Major John B. Bennett, M. C., A. U. S., Los Angeles. The citation stated that as adviser and instructor of the 31st and 51st Medical Battalions Major Bennett "performed meritorious service from December 1941 to April 1942 in Zambales and Bataan, Luzon, Philippine Islands. He constantly visited the field hospitals, collecting stations and battalion aid stations to assure judicious use of the small supplies of medicine and to supervise treatment of the sick and wounded. Through his initiative, excellent judgment and untiring efforts, Major Bennett did much to maintain the best possible health rate and combat effectiveness among the troops in two divisions." Dr. Bennett, a graduate of Baylor University College of Medicine, Dallas, Texas, entered the service Oct. 20, 1940.

VETERANS ADMINISTRATION

ASSIGNMENTS TO TUBERCULOSIS SERVICES

The Veterans Administration has announced the appointment of the following physicians on the tuberculosis services in various Veterans Administration hospitals:

Rodger J. B. Hibbard, Los Angeles, formerly superintendent and medical director, Utah State Tuberculosis Sanatorium. Dr. Hibbard is a specialist certified by the American Board of Internal Medicine.

Harry E. Walkup, Mount Hope, W. Va., formerly chief resident, surgical service, St. Joseph's Hospital, Baltimore.

Meyer Ralph Rosenbloom, Pittsburgh, formerly resident physician at the National Jewish Hospital, Denver, and at the Pennsylvania Tuberculosis Hospital, Cresson, Pa.

Harold H. Rosenbloom, Chicago, formerly associate attending physician in tuberculosis, Cook County Hospital.

Andrew George Goesl, Milwaukee, formerly with the tuberculosis control division, U. S. Public Health Service.

Peter John Galante, Klamath Falls, Ore., formerly assistant director, Henry Phipps Institute, Philadelphia.

Cecil L. Schultz, Philmont, N. Y., formerly medical director, Columbia Sanatorium at Philmont.

Max Baumwell, Belmont, Calif., formerly resident in tuberculosis, California Sanatorium, Belmont, Calif., Central Maine Sanatorium, Fairfield, and State Sanatorium, Booneville, Ark.

Morris C. Thomas, Arlington, Va., formerly resident staff physician, Sunnyside Sanatorium, Indianapolis, and at Essex Mountain Sanatorium, Verona, N. J.

George C. Wilson, Wallingford, Conn., formerly assistant superintendent, Connecticut State Tuberculosis Hospital, Norwich, and assistant in pathology at Yale University, New Haven, Conn.

S. M. Bittinger, Sanatorium, N. C., formerly associate superintendent and medical director of the West North Carolina Sanatorium, Black Mountain. Dr. Bittinger is a specialist certified by the American Board of Internal Medicine.

Frank Peter Ilasi, Brooklyn, formerly house physician, Oakland County Tuberculosis Sanatorium, Pontiac, Mich., and on the visiting staff, Post-Graduate Hospital, Chicago.

William G. Lewis, Winslow, Ariz., formerly physician in charge of the Indian Sanatorium at Albuquerque, N. M.

Andrew Nady, Calumet City, Ill., formerly tuberculosis control physician, state of Illinois, and assistant medical director, Tuberculosis Hospital, Oak Forest, Ill.

Harold Franklin Stolz, Saginaw, Mich., formerly with the Lovelace Clinic, Albuquerque, N. M., and on the staff of St. Joseph's Hospital and Presbyterian Hospital, Albuquerque.

Samuel Phillips, Sanator, S. D., formerly assistant medical director, Los Angeles Sanatorium, Duarte, Calif., and assistant medical director, South Dakota State Sanatorium.

John J. Ahern, Boston, formerly with the sanatorium division, Boston City Hospital, and assistant professor of medicine (tuberculosis), Tufts College Medical School.

PERSONALS

Dr. Roy R. Kracke, dean of Alabama Medical College at Birmingham, has been appointed to an advisory committee comprising eighteen physicians from throughout the United States to aid Gen. Omar Bradley, administrator of the Veterans Administration. The committee will meet four times a year.

Miss Dorothy V. Wheeler, executive secretary of the New York City Nursing Council, has been appointed director of nursing service in the Veterans Administration department of medicine and surgery. Miss Wheeler, a native of Missouri, obtained her R.N. from Washington University, St. Louis, in 1935 and her bachelor of science degree from Ohio State University in 1938.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

ARKANSAS

District Meeting.—The Fifth District Medical Society met in Camden, October 3, to hear the following speakers:

Dr. Paul M. Ramey, Temple, Texas, The Surgical Treatment of Subdiaphragmatic Abscess.
Dr. Clyde A. Stevenson, Temple, Texas, Recent Advances in Treatment of Carcinoma of the Cervix.
Dr. Henry K. Wade, Hot Springs, Legislative Trends.
Dr. William R. Brooksher, Fort Smith, Veterans Administration Program of Medical Care.

CONNECTICUT

Institute of Occupational Medicine.—The establishment of an Institute of Occupational Medicine and Hygiene at Yale University was announced October 29. Dr. Ronald F. Buchan, newly appointed assistant professor of industrial medicine, has been named head of the institute with the title of clinical director, effective November 1. The primary aims of the institute are:

The training of medical students and industrial physicians, based on the belief that occupational medicine and hygiene is now a specialty.

Special graduate instruction, together with the opportunity for research in the field of occupational medicine and hygiene, which will be available to graduate students in medicine, nursing, public health and engineering.

Research in occupational medicine and hygiene, in the belief that the maintenance of active research in such an important field is of teaching value to the intelligent student.

Consultation. The institute will be designed to assist industrial concerns on certain practical questions in the same fashion in which the clinicians in the school of medicine assist their colleagues in the practice of medicine with regard to medical, surgical or public health problems.

The program will be supervised by a committee composed of the following members of the Yale faculty: Dean Blake, serving ex officio; Dr. William T. Salter, professor of pharmacology; Dr. George M. Smith, research associate in anatomy; Ira V. Hiscock, Sc.D., professor of public health, and Dr. John R. Paul, professor of preventive medicine, chairman. This committee will serve as the coordinating group, which will work with Dr. Buchan, the clinical director, in planning the work of the institute at the inauguration of the program. Dr. Buchan, who will sit with the committee, has been practicing industrial medicine in Hartford, where he has been concerned primarily with the organization of medical services for a group of small industrial plants. One of the main teaching functions will be concerned with instruction to all medical students at Yale. This will include special lectures to fourth year students and the opportunity, when the occasion arises, to work as apprentices in well established medical departments of large industries. The special graduate instruction which will be available to graduate students in medicine, nursing, public health and engineering will be integrated and directed by a well organized and special division of the school of medicine. Assistance will also be given in the provision of in-service training courses and in the development of programs for the rehabilitation of workmen convalescent from injury or illness. The research work which the school of medicine and other departments of the university have carried on in subjects allied with industrial medicine will be continued and, where necessary, expanded. These include toxicology, industrial poisons, noxious gases, fumes, dust ventilation and sanitation. In the field of consultation the institute will not compete with the type of service offered by the bureau of industrial hygiene of the Connecticut State Department of Health but will supplement these programs through the facilities of Yale's staff, laboratories and libraries. The facilities of the various schools at Yale concerned with different aspects of occupational medicine will be used as needed. The Connecticut State Medical Society has appointed a committee to serve as liaison with the work of the institute. The members of this committee are Dr. Creighton Barker, New Haven, executive secretary of the society; Dr. Thomas P. Murdock, Meriden, and Dr. Charles F. Yeager, Bridgeport. The initial funds to finance the inauguration of the program were raised through a committee headed by Eugene E. Wilson, Hartford, vice chairman of the United Aircraft Corporation, assisted by F. Thatcher Lane, New Haven, president of the Seamless Rubber Company, who served as vice president.

ILLINOIS

Chicago

University News.—Dr. Einar Lundsgaard, professor of physiology and director of the Institute for Medicine and Physiology, University of Copenhagen, Denmark, lectured at the University of Illinois College of Medicine, October 30, on "Muscle Metabolism."

Medical Technologists.—Ruth Feucht, M.T., was chosen president-elect of the Chicago Society of Medical Technologists at a recent meeting and Helen S. MacVeagh, M.T., was installed as president. Cecelia M. Kortuem, St. Vincent's Infant and Maternity Hospital, 721 North LaSalle Street, is the corresponding secretary. The group meets the third Thursday of each month from October through June. The society is an affiliate of the American Society of Medical Technologists, which will hold its annual convention in the Shirley-Savoy Hotel, Denver, June 30-July 2.

Hamilton Bailey Lectures on Salivary Gland.—Mr. Hamilton Bailey, noted surgeon and fellow of the Royal College of Surgeons, London, England, lectured at the American Hospital, October 30, on "Surgery of the Salivary Glands." The lecture was under the auspices of the Clinical Society of the American Hospital. Mr. Bailey, on conclusion of a tour of the Headquarters of the American Medical Association, October 29, was guest at a luncheon given by officials of the Association. He will speak at the University of Virginia and in other medical centers before returning to England.

INDIANA

Ninety-Seven Years of Age.—Dr. Wilson T. Lawson, Danville, where he has been practicing for sixty-eight years, celebrated his ninety-seventh birthday recently. Dr. Lawson is said to be the oldest living graduate of Wabash College, where he took his premedical work. He has been secretary for many years of the Hendricks County Medical Society and is still in active practice.

KENTUCKY

State Medical Election.—At a recent meeting of the Kentucky State Medical Association Dr. Francis G. Aud, Louisville, was named president-elect and Dr. Elbert W. Jackson, Paducah, was installed as president. Other officers include Drs. Robert W. Robertson, Paducah, Lawrence T. Minish Sr., Frankfort, and Samuel A. Overstreet, Louisville, vice presidents, Dr. Woodford B. Troutman, Louisville, treasurer, and Dr. Philip E. Blackerby, Louisville, secretary. The association's distinguished award went to Dr. Smithfield Keffer, Grayson, who has held every office in the Carter County Medical Society. The E. M. Howard Memorial Award went to Dr. John E. Kincheloe, Hardinsburg, who recently received nationwide publicity when Kincheloe Day was observed in Breckenridge County to honor the physician's forty-seven years of practice. The association adopted a three point hospital standardization program calling for:

Kentucky Medical Association encouragement of efforts of the hospital advisory committee to the state board of health to have enacted a law providing for "minimum hospital standards" in Kentucky.

Establishment at the University of Kentucky and the four state teachers' colleges of first class schools of nursing in conjunction with hospitals in their respective environs.

A survey, if funds are made available, for the study of the educational and other personnel training facilities for the people who must lead our health program.

The hospital standardization committee, composed of Drs. Hugh L. Houston, Murray, William L. Tyler, Owensboro, and Ulysses G. Brummett, Middlesboro, pointed out that Kentucky is one of the few states without laws regulating hospitals and stated that "without such laws it will be ineligible to participate in federal grants and programs."

MASSACHUSETTS

Personal.—Dr. Charles P. Sheldon has been appointed chief of the service of obstetrics and gynecology at the Faulkner Hospital, Jamaica Plain, Boston, and Dr. James A. Halsted chief of the medical service, to succeed Dr. Raymond S. Titus and Dr. Channing Frothingham, who have reached the retirement age.

Changes in Faculty at Boston University.—Lloyd C. Fogg, Ph.D., associate professor of microscopic anatomy, has been appointed registrar at the Boston University School of Medicine, effective at the beginning of the current academic year. Dr. Fogg received his degree of Ph.D. at Columbia University in 1931 and has been a member of the Boston faculty since 1940.——Kenneth E. Penrod, Ph.D., Iowa City, has been appointed assistant professor of physiology at Boston University, effective August 1.

Harvard Expands Public Health Program.—Dr. Hugh R. Leavell, formerly assistant director, division of medical sciences, Rockefeller Foundation, has been appointed to the chair of public health practice at Harvard University Graduate School of Public Health, filling the vacancy that occurred with the death of Dr. Edward G. Huber in July. Dr. John C. Snyder, formerly of New York, has been named to a newly created chair of public health bacteriology. In addition to degrees which presuppose qualifications as doctor of medicine, the school has added the degrees of master of science in hygiene and doctor of science in hygiene, open to investigators. Thus research on problems connected with public health, as well as instruction, will be augmented. During the war Dr. Leavell served as deputy director of health in the European office of UNRRA. Dr. Snyder was a member of the U. S. Typhus Commission when it was organized during World War II. Since his release from the army in 1945 he has been in charge of a program of typhus investigation sponsored by the International Health Division.

MISSOURI

Ernest Sachs Retires.—Dr. Ernest Sachs, a member of the faculty of Washington University School of Medicine, St. Louis, for thirty-five years, has retired as professor of neurologic surgery to become professor emeritus. He will continue his work at Barnes and Children's hospitals and will also continue to train graduate students in neurologic surgery.

District Meeting.—The First Councilor District Society and the St. Joseph Clinical Society held a clinical conference at the Robidoux Hotel, St. Joseph, September 19, under the presidency of Dr. Frederick Gregg Thompson, St. Joseph, for the clinical society and Dr. Harold E. Petersen, St. Joseph, for the district society. Among the speakers were:

Dr. Ronald M. Buck, St. Joseph, Glass Cloth as a Wound Dressing in Orthopedic Surgery.
Dr. Thompson E. Potter, St. Joseph, Treatment of Varicose Veins: Presentation of Two Cases.
Dr. Roy Smith, Rochester, Minn., Treatment of Cardiac Failure.
Raymond McIntyre, St. Louis, State Medical Association Problems.
F. Kenneth Helsby, Kansas City, Prepaid Hospitalization and Medical Care.
Dr. Herbert C. Miller, Kansas City, Recent Advances in the Study of Rheumatic Fever.
Dr. James O'Donoghue, St. Joseph, Intrathoracic Calcifications.
Dr. Wilbur P. McDonald, St. Joseph, Wound Closure in Compound Fractures.
Dr. James B. Brown, St. Louis, Military Plastic Surgery.
Dr. Howard B. Goodrich, Hannibal, Program of the Missouri State Medical Association.

Appointment in Occupational Therapy.—Miss Sue Hurt, field secretary of the American Occupational Therapy Association and for several years director of the department of occupational therapy of the Richmond Professional Institute of the College of William and Mary, Richmond, Va., has been appointed director of the department of occupational therapy, Washington University School of Medicine, St. Louis. The department was started in 1918 as the St. Louis School for Reconstruction Aides and is said to be the first training center of its kind west of the Mississippi. In 1919 the name was changed to the St. Louis School of Occupational Therapy. Extension of the program was made possible in 1934 by an association with Washington University, and the name was again changed to St. Louis School of Occupational and Recreational Therapy. A subsequent bequest by Rachel Stix Michael brought about a closer affiliation with the university, and in February 1946 the school was established as a department in the division of auxiliary medical services. This division is conducted under the direction of the dean and the executive faculty of Washington University School of Medicine.

NEW YORK

New Tumor Service.—Dr. Lionel S. Auster, attending surgeon at the Bronx Hospital, has been named head of the newly created tumor service at the hospital. The service is replacing the former tumor clinic and conference unit which he headed prior to his entrance into the naval service in 1941, operations of which were suspended during the war years. The new department, which will provide comprehensive diagnostic, teaching and treatment service for both ambulant and inpatient oncologic cases, was to start functioning in October.

Faculty News.—Elmer H. Stotz, Ph.D., head of the division of food science and technology at the New York State Agricultural Experiment Station, Geneva, has been appointed professor of biochemistry and chairman of the department of biochemistry, University of Rochester School of Medicine and Dentistry. He will succeed Walter R. Bloor, Ph.D., professor of biochemistry and pharmacology and associate dean of the school of medicine when Dr. Bloor retires from the faculty next June. Dr. Bloor has been a professor at the medical school since 1922. Dr. Stotz joined the Agricultural Experiment Station staff in 1943 after serving for five years as director of laboratories of McLean Hospital and instructor in biochemistry at Harvard Medical School, where he specialized in investigations of tissue metabolism and enzyme chemistry. Appointed as head of the division of chemistry at the experiment station to succeed Donald K. Tressler, Ph.D., Dr. Stotz was named head of the division of food science and technology in 1945 when the new division was created by the board of trustees of Cornell University by merging the divisions of bacteriology and chemistry.

New York City

Changes in Health Personnel.—Dr. George James, assistant district health officer of Middletown, was appointed to a similar position for Greene and Ulster counties with headquarters at Kingston, effective September 1. Dr. James succeeds Dr. Berwyn F. Mattison, Albany, who resigned to become health officer of Yonkers (The Journal, October 19, p. 400).

Normal and Atypical Pigment Cell Growth.—A conference on the biology of normal and atypical pigment cell growth will be held November 15-16 at the American Museum of Natural History under the auspices of the section of biology of the New York Academy of Sciences. Among the speakers will be:

Dr. George T. Pack, The Melanoma Problem.
Graham P. DuShane, Ph.D., Palo Alto, Calif., Origin and Development of the Melanophores.
Dr. Glenn H. Algire, Bethesda, Md., Growth and Vascular Reactions of Transplanted Mouse Melanomas.
James B. Hamilton, Ph.D., Brooklyn, Influence of the Endocrine Status on Pigmentation in Man and in Mammals.
Frank H. J. Figge, Ph.D., Baltimore, Chemical Nature of Melanin.
Jesse P. Greenstein, Ph.D., Bethesda, Md., Chemistry of Melanomas.
Dr. Dennis L. Fox, La Jolla, Calif., Some Features of Melanoid Biochromy in Animals.

Faculty Appointments and Promotions.—Dr. James M. Winfield, associate professor of surgery, Wayne University College of Medicine, Detroit, has been appointed professor of surgery, attending surgeon and educational director of the department of surgery at the New York Medical College, Flower and Fifth Avenue Hospitals. During World War II, Dr. Winfield served as a colonel in the Army Medical Corps. He was surgical chief of the 36th General Hospital and Hospital Center consultant. He will have as deputies in each of the hospitals affiliated with the college the following, who will assist with the daily supervision and direction of the teaching program in those institutions: Dr. Walter L. Mersheimer, assistant professor of surgery, who will be assigned at the Metropolitan Hospital; Dr. Allan S. Graham, instructor in surgery, assigned to the Flower and Fifth Avenue Hospitals, and Dr. Nicholas Tiscione, assistant clinical professor, assigned to the Queens General Hospital. The assignment to the City Hospital has not yet been made. Claude M. McFall, Ph.D., who has been head of the anatomy department at George Washington University School of Medicine, Washington, D. C., since 1939, has been appointed visiting professor of anatomy for the current academic year. New appointments include Dr. Preston A. Wade, clinical professor of surgery; Dr. James H. Kidder, associate clinical professor of surgery; Dr. Wilfred F. Ruggiero, associate clinical professor of surgery, and E. Lawrence House, Ph.D., assistant professor of anatomy. Promotions include:

Roger C. Gay, Ed.M., assistant dean.
James W. Benjamin, Ph.D., professor of anatomy and assistant to the dean.
Lois C. Lillick, Ph.D., associate professor of bacteriology and active director of the department.
Dr. Francis D. Speer, associate professor of clinical pathology and director of the laboratory.
Dr. Lawrence B. Slobody, associate professor in pediatrics and associate attending pediatrician.
Dr. Charles A. Turtz, associate clinical professor of ophthalmology and associate attending ophthalmologist.
Dr. Herman Robbins, assistant professor of pediatrics and assistant attending pediatrician.
Dr. Jerome G. Kaufman, assistant professor of medicine and assistant attending physician.
Dr. Samuel L. Saltzman, assistant clinical professor of ophthalmology.

OKLAHOMA

New Position as Health Consultant.—Milton L. Shurr, formerly health consultant in Omaha, has been named director of public health education and coordination for Tulsa County, a newly created position within the Tulsa City Health Department. One of Mr. Shurr's activities will be to coordinate functions of health and welfare agencies in the city. According to the *Bulletin* of the Tulsa County Medical Society the present experimental setup for three years is hoped to become a permanent part of health education activities in Tulsa. The position is jointly sponsored by the Tulsa Council of Social Agencies and participating members.

PENNSYLVANIA

Personal.—Dr. Merl G. Colvin, Williamsport, medical director of Lycoming County for the past seven years, has been appointed a member of the state advisory health board.

Philadelphia

Annual Banquet.—The sixtieth annual banquet of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital will be held on Tuesday, December 3, at the Bellevue-Stratford Hotel, Broad and Walnut streets. The guest of honor will be Dr. Edward A. Schumann. Reservations may be had by writing to the secretary-treasurer, Dr. Robert C. McElroy, 133 South 36th Street, Philadelphia 4.

Esmond Long Named Director of Research for Tuberculosis Association.—Dr. Esmond R. Long, director of the Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis, has been appointed director of research of the National Tuberculosis Association. Dr. Long was president of the association in 1936 and has been a member of its Committee on Medical Research since 1929. He received the Trudeau Medal for tuberculosis research in 1932.

TEXAS

State Medical Election.—At a recent meeting of the State Medical Association of Texas Dr. Britton E. Pickett Sr., Carrizo Springs, was chosen president-elect, and Dr. Claude C. Cody Jr., Houston, was installed as president. Other officers include Drs. Samuel D. Whitten, Greenville, Charles P. Yeager, Corpus Christi, and James M. Campbell, Goldthwaite, vice presidents, Dr. Holman Taylor, Fort Worth, secretary and Dr. Khleber H. Beall, Fort Worth, treasurer.

University News.—A new course dealing with the applications of physics to physiology and medicine has been inaugurated at the University of Texas Medical Branch, Galveston, under the auspices of the departments of physiology and radiology. The new course is designed as an orientation course for first year. students and will be given once weekly during the first semester. Howard G. Swann, Ph.D., assistant professor of physiology at the University of Texas, has received a grant of $10,000 from the Army Research Program for studies on aviation physiology. During the war Dr. Swann was associated with the Aviation Physiology Laboratories at Wright Field. The grant is for the purpose of assisting in the continuance of studies undertaken by Dr. Swann while at Wright Field. Wilbur A. Selle, Ph.D., professor of physiology at the medical branch, is surveying American medical centers under the auspices of the Baruch Committee for Physical Medicine in order to develop satisfactory methods for teaching the medical application of physics to undergraduate medical students. Dr. Truman G. Blocker Jr., on terminal leave as colonel in the Medical Corps of the U. S. Army, and formerly in charge of Wakeman General Hospital, Camp Atterbury, Ind., is returning to the University of Texas Medical Branch as professor of plastic and maxillofacial surgery. W. D. Collings, Ph.D., has resigned as professor of physiology at the University of Texas Medical Branch to become assistant professor of physiology at the State University of Iowa College of Medicine, Iowa City, and Dr. Stephen Weisz has resigned as associate professor of neuropsychiatry and assistant director of the State Psychopathic Hospital to become associate professor of neuropsychiatry at Southwestern Medical College, Dallas.

VERMONT

State Medical Election.—Dr. Benjamin F. Cook, Rutland, was named president-elect of the Vermont State Medical Society at its meeting in Burlington, October 2. Dr. Cook will not take office as president until 1948. Dr. Frank C. Angell, Randolph, was installed as president. Other officers elected are Dr. Hiram E. Upton, Burlington, vice president, Dr. Theodore H. Harwood, Burlington, secretary, and Dr. David Marvin, Essex Junction, treasurer. The establishment of a state health council to coordinate the work of the society with other health agencies and with labor, agriculture and industry was advocated by the house of delegates. It was also decided to develop and extend a voluntary prepayment medical care plan throughout the state and support the college of medicine of the University of Vermont in its effort to provide training to physicians for rural areas.

WEST VIRGINIA

Publicity Director for Cancer Control.—Calvert L. Estill, Charleston, has been appointed publicity director for the West Virginia Cancer Society, effective October 1. Mr. Estill, who was formerly director of public welfare of West Virginia, is staff correspondent for the Ogden chain of newspapers.

Effect of Prenatal Blood Test Law.—Since the prenatal blood test law became effective in July 1945, 80 per cent of the expectant mothers in the state have received a blood test for syphilis prior to the birth of their children. However, of this number only about 40 per cent were given the test on or before the fifth month of pregnancy, notwithstanding the fact that health authorities have emphasized the importance of having the test made before the fifth month to avoid if possible the hazards of miscarriages, stillbirths or congenital syphilis. Of the 36,071 expectant mothers examined during the fiscal year ended June 30, 674 were found to have syphilis. While 514 were new cases which were placed under treatment, 160 expectant mothers had previous knowledge of the disease. In a recent address Mr. E. J. Hall, educational consultant for the bureau of venereal disease control, state health department, said that "the low percentage of expectant mothers receiving blood tests in the first five months of pregnancy indicates that only a small number of women are receiving proper prenatal care in West Virginia and no doubt partly accounts for the fact that West Virginia's infant mortality rate is 30 per cent higher than the United States as a whole." Mr. Hall reported that 5 per cent of all deliveries in West Virginia are performed by licensed midwives. The act itself makes no provision for blood tests by midwives, but county and district health officers are charged with the duty of obtaining blood specimens for performing serologic tests for syphilis. There is no charge for this service, and examinations are made also without charge at the state hygienic laboratory. The law goes further than this and provides that in areas where there is no county or district health officer the state health department is to assume the responsibility of obtaining specimens without charge to pregnant women.

WISCONSIN

Annual Dearholt Day.—The seventh annual Dearholt Day, presented for the medical students and the general medical profession of Wisconsin by the Wisconsin Anti-Tuberculosis Association, will be held November 18 in Madison and November 19 in Milwaukee. The program will be presented in both cities by Sol R. Rosenthal, Major, M. C., chief of laboratory service, Bruns General Hospital, Santa Fe, N. M., on "BCG in Tuberculosis," and Dr. Julius L. Wilson, associate professor of medicine, Tulane University of Louisiana School of Medicine, New Orleans, on "Cause of Apical Localization of Tuberculosis and Its Implications for Treatment." Dr. Wilson will also speak on "Pulmonary Emphysema: Pathologic Physiology and Treatment." Cooperating in both programs are the Marquette University School of Medicine, Milwaukee; University of Wisconsin Medical School, Madison; Milwaukee Academy of Medicine, Dane County Medical Society and Wisconsin Trudeau Society.

GENERAL

A. A. A. S. Moves Into New Home.—The American Association for the Advancement of Science on September 9 began moving into its new home at 1515 Massachusetts Avenue N.W., Washington 5, D. C. The administrative offices and the editorial office of the *Scientific Monthly* were transferred from the Smithsonian Institution building to the new site, and the editorial office of *Science* and the office of the advertising department were removed from a "temporary building" (constructed in 1917) of the War Department on the campus of the American University several miles distant in the western part of the city.

Aero-Medical Association.—Membership in the Aero-Medical Association of the United States is open to qualified applicants who have some active interest in aviation medicine. This announcement is directed especially to those flight surgeons who are now C. A. A. examiners or who perform flight physical examinations for private individuals or for flight personnel connected with commercial flying. Inquiries may be directed to Dr. Ludwig G. Lederer, medical director, Capital Airlines, Washington National Airport, Washington 1, D. C., who represents civilian interests on the membership committee of the Aero-Medical Association of the United States.

Hermann Muller Awarded Nobel Prize.—Hermann J. Muller, Ph.D., professor of zoology, Indiana University, Bloomington, has been awarded the Nobel Prize in medicine and physiology, it was announced October 31, for his work in discovering that "mutations, or biological changes in species, may be produced by x-rays." Dr. Muller's research throughout his career has been concerned with mutations and evolution. He joined the Indiana University staff in 1945, having resigned as professor of biology at Amherst College. Newspaper reports announce that the Rockefeller Foundation granted $95,000 to Indiana University last year for a six year research program in the field of genetics, and Dr. Muller was named as one of three scientists to conduct it. The American Cancer Society made a grant of $4,500 to Dr. Muller last week for the study of cancer.

Prize in Gastroenterology.—The National Gastroenterological Association announces its annual cash prize award contest for 1947. One hundred dollars and a certificate of merit will be given for the best unpublished contribution on gastroenterology or allied subjects. Certificates will also be awarded those physicians whose contributions are deemed worthy. Contestants residing in the United States must be members of the American Medical Association. Those residing in foreign countries must be members of a similar organization in their own country. The winning contribution will be selected by a board of impartial judges, and the award is to be made at the annual convention banquet of the National Gastroenterological Association in June of 1947. Certificates awarded to other physicians will be mailed to them. All entries for the 1947 prize should be limited to 5,000 words, typewritten in English, prepared in manuscript form, submitted in five copies, accompanied by an entry letter, and must be received not later than April 1, 1947. Entries should be addressed to the National Gastroenterological Association, 1819 Broadway, New York 23.

International Hematology and Rh Conference.—The International Hematology and Rh Conference will be held in Dallas, Texas, November 15-16 under the auspices of Baylor Hospital, Dallas, and in affiliation with the second Mexican Blood Transfusion Congress, which is to be held during the following week. Dr. Joseph M. Hill, Dallas, will preside at the opening session, at which speakers will be Dr. Ignacio Gonzalez Guzman offering greetings from Mexico, Dr. William L. Hart greetings from Dallas and Mr. Lawrence R. Payne a welcome from Baylor Hospital. Other speakers on the program will include:

Dr. Philip Levine, Linden, N. J., Brief Survey of the Significance of the Rh Factor.
Dr. Ernest Witebsky, Buffalo, Interrelationship Between the Rh System and the A B System.
Dr. Guzman, Nuclear Structure of the Blood Cells.
Dr. Robert R. Race, London, England, The Rh Genotypes and Fisher's Theory.
Dr. Hill, Evidence for Rh Antibodies Differing from the Agglutinating Types.
Dr. William Dameshek, Boston, Hemolytic Mechanisms.
Dr. Louis K. Diamond, Boston, Physicochemical and Immunologic Characteristics of Rh Antibodies.
Dr. Israel Davidsohn, Chicago, Rh Antibodies.
Dr. Ludwig Hirszfeld, Wroclow, Poland, The Constitution, Heredity and Terminology of the Subgroups.

There will also be a round table discussion with Dr. Levine presiding. At the banquet Dr. Eduardo Uribe Guerola, Mexico, D. F., Mexico, will be the principal speaker on "The Transfusion Congress."

Educational Program on Diseases of the Heart.—The initiation of a nationwide program of public education and information on diseases of the heart was announced October 4 by the American Heart Association, 1790 Broadway, New York. The object of the campaign is "the dissemination of educational information to the public in a broad effort to retard the rapid increase of heart disease throughout the nation." The program calls for emphasis on educational work with schools, parent-teachers' associations and other groups concerned with children because of the importance of rheumatic fever and heart disease. According to recent surveys, this scourge of children causes more than five times as many deaths as the combined total of deaths from infantile paralysis, scarlet fever, diphtheria, measles, meningitis and whooping cough. It is a serious disease among adults too, as illustrated by the estimated 40,000 veterans who acquired the disease during their recent military service. The educational campaign of the American Heart Association will reach its climax during the National Heart Week to begin on February 9, which includes St. Valentine's day. It is expected that all branches of medicine, pharmacy, insurance, industry and many other groups interested in health and public welfare will cooperate fully. Supporting and cooperating groups will include the following national organizations, which comprise the American Council on Rheumatic Fever of the American Heart Association:

American Academy of Pediatrics.
American Association of Medical Social Workers.
American College of Physicians.
American Hospital Association.
American Medical Association.
American Nurses Association.
American Public Health Association.
American Rheumatism Association.
American School Health Association.
National Organization for Public Health Nursing.
National Society for Crippled Children and Adults.

Special Society Elections.—At the annual meeting of the American Diabetes Association Dr. Russell M. Wilder, Rochester, Minn., was chosen president. Other officers include Drs. Edward S. Dillon, Philadelphia, and Charles H. Best, Toronto, Ont., Canada, vice presidents, Dr. Cecil Striker, Cincinnati, secretary, and Dr. William Muhlberg, Cincinnati, treasurer. The next meeting of the association will be held in Atlantic City in June.——Dr. Robert D. Mussey, Rochester, Minn., was chosen president-elect of the American Association of Obstetricians and Gynecologists in Hot Springs, September 5-7. Dr. Archibald D. Campbell, Montreal, Quebec, was installed as president. Other officers include Dr. Adam P. Leighton, Portland, Maine, vice president, Dr. James R. Bloss, Huntington, W. Va., secretary, reelected, Dr. Leroy A. Calkins, Kansas City, Mo., assistant secretary, and Dr. Ward F. Seeley, Detroit, treasurer. The 1947 meeting will be held at the Homestead, Hot Springs, September 4-6.——At a recent meeting of the Central Association of Obstetricians and Gynecologists Dr. William F. Mengert, Dallas, Texas, was named president-elect, and Dr. Earl C. Sage, Omaha, was installed as president. Other officers include Dr. George Kamperman, Detroit, vice president; Dr. John I. Brewer, Chicago, secretary-treasurer, and Dr. Harold L. Gainey, Kansas City, Mo., assistant secretary. The 1947 meeting of the association will be held in Louisville, Ky., the exact dates to be determined later.——Dr. Frank R. Bradley, St. Louis, was recently elected president of the American College of Hospital Administrators.——At a recent meeting of the American Broncho-Esophagological Association Dr. Robert M. Lukens, Philadelphia, was elected president. Other officers include Dr. Murdock S. Equen, Atlanta, Ga., vice president; Dr. Paul H. Holinger, Chicago, secretary, and Dr. Clyde A. Heatly, Rochester, N. Y., treasurer.

Marriages

Peter Nicholas Horvath, Bethesda, Md., to Miss Irene Kulig of Thorp, Wis., in Forest Glen, Md., August 10.

Daniel Elliott Mack, Windsor, Conn., to Miss Elizabeth Thomas of Mobile, Ala., in Syracuse, N. Y., June 23.

Rodney Robert Gleysteen, Alton, Iowa, to Miss Laura Hannah Funnell in Chula Vista, Calif., September 2.

Virgil Shields LeQuire, Rochester, N. Y., to Miss Louise Fairfax Lasseter of Nashville, Tenn., August 20.

Sidney Ourin Krasnoff, Philadelphia, to Miss Ruth Buchsbaum Bernstein of Elkins Park, June 11.

William Riley Snow, Abilene, Texas, to Mrs. William Emmett Ryan in Amarillo, September 1.

Edward L. Rohlf to Miss Lorene Lindaman, both of Waterloo, Iowa, at Cedar Rapids in August.

Carroll K. Clawson, Grand Rapids, Mich., to Miss Doris Marie Bowman of Kalamazoo, July 2.

Gaston E. Blom, Bronxville, N. Y., to Miss Dorothy Ruth Engstrand of Douglaston, July 20.

Robert Nelson Jr. to Mrs. Frances Franke McNutt, both of Birmingham, Ala., in August.

Louis J. Noun, Des Moines, to Miss Ellen Miles of Alexandria, Va., in Chicago, June 28.

Thomas Kermit Hepler, Harrisburg, Pa., to Dr. Jeanne L. Truter of Danville, June 6.

Edward Olin White, Ehrhardt, S. C., to Miss Ruth Griffin of Charleston, July 12.

Basil B. Dulin to Miss Julia Louise Guess, both of Indianapolis, May 26.

William S. Judy to Mrs. Daisy S. Guy, both of Greenville, S. C., June 8.

Naftula Izbicki to Miss Rose Malekow, both of Chicago, August 11.

Deaths

Clement Buchanan Masson ⊕ New York; George Washington University School of Medicine, Washington, D. C., 1921; born in Newburgh, N. Y., Feb. 2, 1898; assistant professor of clinical neurosurgery at the Columbia University College of Physicians and Surgeons; specialist certified by the American Board of Neurological Surgery; member of the American Psychiatric Association and the Association for Research in Nervous and Mental Disease; fellow of the American College of Surgeons; on the staff of the Neurological Institute of New York; on the staffs of the Grasslands Hospital, Valhalla; consulting neurosurgeon, Vassar Brothers Hospital, Poughkeepsie, Northern Westchester Hospital in Mount Kisco, N. Y., and the Hackensack (N. J.) Hospital; died in the Doctors Hospital, September 5, aged 48.

Herman Grove Difenderfer ⊕ Johnstown, Pa.; Medico-Chirurgical College of Philadelphia, 1911; born in Milton, Pa., Aug. 9, 1886; member of the staffs of the Conemaugh Valley Memorial and Mercy hospitals; served as director of the First National Bank in Beaverdale and as director of the Portage National Bank; medical inspector of the schools in Beaverdale, Wilmore and Summerhill since 1918 and a member of the Summerhill Township school board since 1925; member of the draft board at South Fork during World War I and chairman of Cambria County Selective Service Board number 5, South Fork, during World War II; received a Presidential Citation for his services; died September 5, aged 60, of bronchial asthma.

George Henry Semken ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1896; member of the founders group of the American Board of Surgery; an adviser to the New York Institute of Clinical Oral Pathology; fellow of the New York Academy of Medicine and the American College of Surgeons; member of the New York Surgical Society and the New York Pathological Society; member of the executive committee of the American Cancer Society; consultant, New York City Cancer Institute Hospital; consulting surgeon to the Institute of Cancer Research, Columbia University and the Knickerbocker Hospital, where he died September 16, aged 71.

Dennett L. Richardson ⊕ Providence, R. I.; University of Pennsylvania Department of Medicine, Philadelphia, 1905; member of the House of Delegates of the American Medical Association in 1913; served as president of the Hospital Association of Rhode Island and superintendent of health of Providence; author of "Infectious Diseases and Aseptic Nursing Technique"; formerly superintendent of the Providence City Hospital, which later changed its name to the Charles V. Chapin Hospital, where he was also superintendent; for many years superintendent of the Rhode Island Hospital, where he died September 6, aged 66.

Carl Goodwin Burdick ⊕ Wilton, Conn.; Columbia University College of Physicians and Surgeons, New York, 1903; clinical professor of surgery at the New York University College of Medicine; member of the American Surgical Association; fellow of the American College of Surgeons and the New York Academy of Medicine; past president of the New York Surgical Society; member of the founders group of the American Board of Surgery; served overseas during World War I; on the staffs of the Bellevue Hospital and the Hospital for Special Surgery, both in New York; died September 1, aged 66, of heart disease.

Foster Miller Routh ⊕ Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1910; served as member, chairman and for many years member of the executive committee of the state board of health; past president of the Columbia Medical Society; served during World War I; at one time associated with the Rockefeller Sanitary Commission and the International Health Board; first health officer of Greenwood County; for many years affiliated with the Columbia Hospital; served as resident physician at the University of South Carolina; died in Varnville September 10, aged 61.

Edward Joseph Agnelly ⊕ Detroit; Detroit College of Medicine, 1903; served during World War I; died September 5, aged 68, of bronchopneumonia.

Jacob S. Allen, Chester, S. C.; Leonard Medical School, Raleigh, 1902; died in Philadelphia September 20, aged 73.

Alton Louis Amsterdam, New York; University and Bellevue Hospital Medical College, New York, 1919; on the staffs of the Mount Sinai Hospital and the Beth Israel Hospital; died October 2, aged 49, of hypertensive cardiovascular disease and coronary occlusion.

Henry Thompson Bailey, Phoenix, Ariz.; Hospital College of Medicine, Louisville, Ky., 1903; fellow of the American College of Surgeons; on the staffs of St. Joseph's Hospital and the Good Samaritan Hospital, where he died September 16, aged 72, of carcinoma of the sigmoid.

Roy Frank Barker, Wood River, Ill.; Barnes Medical College, St. Louis, 1907; member of the American Medical Association; served during World War I; served as St. Clair County physician and coroner; died in Alton September 11, aged 61, of coronary thrombosis.

John Thomas Batte ⊕ Covington, Ky.; Medical College of Ohio, Cincinnati, 1906; found dead in bed September 18, aged 62.

Nathaniel Morrel Benyas ⊕ Honolulu, Hawaii; Northwestern University Medical School, Chicago, 1912; served as vice president of the Hawaii Territorial Medical Association; past president of the Honolulu County Medical Society; served during World War I; died in San Francisco September 7, aged 60.

Charles Willard Burnell, Bridgton, Maine; Baltimore Medical College, 1896; died September 13, aged 84.

John Thomas Carpenter, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1889; member of the American Medical Association and the American Ophthalmological Society; formerly lecturer in ophthalmology at his alma mater and on the staffs of the University Hospital and the Bryn Mawr (Pa.) Hospital; died in Radnor September 16, aged 79.

Benedetto Ciaffo, West New York, N. J.; Regia Università degli Studi di Palermo Facoltà di Medicina e Chirurgia, Italy, 1902; died September 11, aged 73.

Irving Sherburne Cook, Georgiaville, R. I.; Harvard Medical School, Boston, 1886; member of the American Medical Association; for many years health officer; served on the town school committee and as town superintendent of schools; the Irving S. Cook School was named in his honor; died September 9, aged 88, of arteriosclerotic heart disease.

Lyman Driesbach ⊕ Middleburg, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York, 1908; past president of the Schoharie County Medical Society; at various times mayor of Middleburg; died September 3, aged 65.

Ellis Edwin Foster, New Bedford, Mass.; Tufts College Medical School, Boston, 1902; fellow of the American College of Surgeons; died in St. Luke's Hospital September 10, aged 74.

Joshua Francis Fraser, Memphis, Tenn.; Missouri College of Medicine and Science, St. Louis, 1929; member of the American Medical Association; served in France during World War I; died in St. Joseph's Hospital September 17, aged 53.

Ernest Sipe Gasteiger, Los Angeles; Jefferson Medical College of Philadelphia, 1927; member of the American Medical Association; lieutenant commander in the medical corps of the Naval Reserve, not on active duty; on the staff of the California Hospital; died in the Veterans Administration Facility, West Los Angeles, September 14, aged 46.

Jesse Hunnel Hazlett, Waynesburg, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1900; member of the American Medical Association; served during World War I; on the staff of the Greene County Memorial Hospital; died September 14, aged 73, of diabetes mellitus and coronary thrombosis.

Robert Lee Huddleston, Deatsville, Ala.; University of Georgia Medical Department, Augusta, 1890; member of the American Medical Association; formerly senator; died September 17, aged 82.

Harold Carl Joesting, Los Angeles; University of Minnesota Medical School, Minneapolis, 1929; member of the American Academy of Pediatrics; died September 18, aged 42.

Thomas Barnett Lewis Jordan, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1900; for many years medical examiner and company surgeon of the Pennsylvania Railroad; died in Atlantic City, N. J., September 5, aged 72.

Edward N. Kingsbury, Hamden, Conn.; Hahnemann Medical College of Philadelphia, 1880; died October 4, aged 93, of bronchopneumonia.

Charles Augustus Martin, Terry, Miss.; Mississippi Medical College, Meridian, 1910; served during World War I; died August 24, aged 66.

Josiah Libby Millett, Seattle; University of Minnesota College of Medicine and Surgery, Minneapolis, 1902; member of the American Medical Association; died in Edmonds August 27, aged 69.

Robert L. Moberly, Olathe, Kan.; Medico-Chirurgical College of Kansas City, 1900; *member of the American Medical Association;* died May 11, aged 74.

Lawrence Gray Patterson, Memphis, Tenn.; Meharry Medical College, Nashville, 1905; died August 31, aged 67.

Frederick Johnson Peck, Ansonia, Conn.; University of Michigan Homeopathic Medical School, Ann Arbor, 1892; died August 22, aged 79.

Nathan Avery Peyton, Hartsville, Tenn.; Meharry Medical College, Nashville, 1917; served during World War I; died in the George W. Hubbard Hospital of Meharry Medical College, Nashville, August 16, aged 59.

John W. Pickel, Kirkwood, Mo.; College of Physicians and Surgeons, Baltimore, 1884; member of the American Medical Association; honorary member of the Missouri State Medical Association; past president of the Jefferson County Medical Society, of which he had been an honorary member; died September 13, aged 91, of cardiac failure.

William H. Roberts ⚕ Sheridan, Wyo.; Northwestern University Medical School, Chicago, 1901; formerly secretary of the Wyoming State Medical Society; past president of the Sheridan County Medical Society; on the staff of the Sheridan County Memorial Hospital; died July 25, aged 72.

Pleasant W. Rose, Cypress, Ill.; Barnes Medical College, St. Louis, 1899; died August 29, aged 69.

Thomas Andrew Roselle, Palmyra, Mo.; Hospital College of Medicine, Louisville, 1903; member of the American Medical Association; served during World War I; died in the Levering Hospital, Hannibal, September 7, aged 70, of myocarditis.

Alex Morton Rosenblum ⚕ Youngstown, Ohio; University of Pennsylvania School of Medicine, Philadelphia, 1912; served during World War I; served on the staff of St. Elizabeth's Hospital; died September 6, aged 56, of myocardial infarction.

Carl August Samuelson ⚕ Sheldon, Iowa; State University of Iowa College of Medicine, Iowa City, 1923; served during World War I; at one time affiliated with the Hull Hospital in Hull; died in St. Joseph Mercy Hospital, Sioux City, September 15, aged 53, of congestive heart failure following pneumonia.

Harmon Ulysses Sanders ⚕ Carrollton, Miss. (licensed in Mississippi in 1904); *died in Grenada August 16, aged 73.*

Julius A. Schmidt, Milwaukee; Milwaukee Medical College, 1904; member of the American Medical Association; died September 11, aged 70, of carcinoma of the sigmoid.

Rudolph Schwarz, Brooklyn; Medizinische Fakultät der Universität Wien, Vienna, Austria, 1914; served during World War II as medical consultant for one of the Selective Service boards in Bay Ridge and recently received a medal from the government for his five years' service; died in the Montefiore Hospital, New York, August 2, aged 59.

Jesse Evans Shull, Alpena, S. D.; Sioux City College of Medicine, 1898; *member of the board of directors and for many* years president of the Bank of Alpena; died in the Methodist Hospital, Mitchell, July 12, aged 77.

Elwood Shellenberger Snyder, Norristown, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1896; served on the board of health in Lancaster, where he was on the staff of St. Joseph's Hospital; died August 17, aged 78.

Samuel Mott Souders ⚕ Red Lodge, Mont.; Medical College of Ohio, Cincinnati, 1900; died August 29, aged 72.

John W. Speck, Jackson, Mich.; Detroit College of Medicine and Surgery, 1926; member of the American Medical Association; at one time affiliated with the Michigan State Prison Hospital in Jackson; on the staffs of the Mercy Hospital and the W. A. Foote Memorial Hospital, where he died September 8, aged 43, of pulmonary embolism.

Elmer S. Stambaugh, York, Pa.; College of Physicians and Surgeons, Baltimore, 1910; member of the American Medical Association; died July 18, aged 68.

Patricia H. Steen, Hempstead, N. Y.; University of Aberdeen Faculty of Medicine, Scotland, 1921; member of the American Medical Association and the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology, Inc.; consultant, Nassau Hospital, Mineola, where she died September 15, aged 47, of cerebral hemorrhage.

Newton Henry Stein ⚕ Silver Creek, Pa.; Medico-Chirurgical College of Philadelphia, 1904; president of the Silver Creek State Bank; on the staff of the Good Samaritan Hospital, Pottsville; died in the Jefferson Hospital, Philadelphia, August 16, aged 69.

Aubon Earl Stewart, Los Angeles; Manitoba Medical College, Winnipeg, Man., Canada, 1913; member of the American Medical Association; died August 31, aged 59.

Frederick Bismarck Strauss ⚕ Bismarck, N. D.; Rush Medical College, Chicago, 1901; in the Indian Service; died July 26, aged 67.

Joseph Lawn Thompson, Washington, D. C.; George Washington University School of Medicine, Washington, 1912; member of the American Medical Association; served on the faculty of his alma mater and the Georgetown University School of Medicine; formerly on the staff of the Providence Hospital and medical director of the Catholic University; died in the Washington Home for Incurables September 3, aged 72, of cerebral arteriosclerosis.

Walter Elbert Thorpe, Bristol, Conn.; New York Homeopathic Medical College, 1885; died August 20, aged 87.

John Samuel Turberville ⚕ Century, Fla.; Medical College of Alabama, Mobile, 1902; *member of the Southeastern* Surgical Association; fellow of the American College of Surgeons; past president of the Florida Medical Association and the Escambia County Medical Society; medical superintendent of the Turberville Hospital; killed September 21, aged 71, when the automobile in which he was driving collided with a truck near Atmore, Ala.

Donald C. Urie ⚕ Camas, Wash.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; affiliated with St. Joseph's Hospital in Vancouver; died July 9, aged 67.

Henry Palmerston Vaughan, Brooklyn; *Columbia University* College of Physicians and Surgeons, New York, 1897; died August 8, aged 81.

William Henry Walker, New York; Georgetown University School of Medicine, Washington, D. C., 1902; served as physician for the New York State Athletic Commission; died August 28, aged 67, of cerebral hemorrhage.

Thomas F. Walsh, Chicago; Chicago Medical School, 1917; died September 14, aged 57.

George Louis Weinstein ⚕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1905; died July 25, aged 73.

Timothy Daniel Welch, Collins, Miss.; University of Nashville Medical Department, 1905; died in the South Mississippi Infirmary, Hattiesburg, July 21, aged 68.

Daniel J. Williams, Gulfport, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1890; member of the American Medical Association, serving as a member of its House of Delegates in 1904 and 1905; past president of the Mississippi State Medical Association; secretary, Harrison-Stone Counties Medical Society; for many years county health officer; formerly member of the state board of health; director of the Claiborne County Health Department; died September 2, aged 78.

U. S. PUBLIC HEALTH SERVICE

Robert Henry Onstott ⚕ Medical Director, U. S. Public Health Service, San Francisco; born in Colorado Springs, Colo., on Nov. 30, 1905; entered the public health service directly after graduating from the University of Colorado School of Medicine in Denver in 1930; served an internship at the U. S. Marine Hospital; accepted his original commission as assistant surgeon in the regular corps on July 1, 1933; his assignments have included hospital duty, nutrition research, county and state health department work and postgraduate training in public health and venereal disease control at Johns Hopkins University; from September 1940 to March 1942 was detailed as a technical adviser to the governor of Louisiana, aiding in the reorganization of the state health department; until proceeding to Hawaii was assigned as liaison officer to the Fourth Army Command with headquarters in Atlanta; had just returned to this country after three years' service as director of the U. S. Public Health Service District number 10 with headquarters in Honolulu, Hawaii; in that capacity he acted as adviser to the governor of Hawaii and the Territorial Health Department in matters relating to public health administration; killed in an automobile accident near Auburn, Calif., September 4, aged 40, while en route to Washington, D. C., for reassignment as chief of the division of commissioned officers of the U. S. Public Health Service.

The Mechanism of Headache

In a paper read at Guy's Hospital and published in its *Gazette*, Sir Charles Symonds pointed out that it is only in the last few years that we have had any clear idea of the mechanisms of headache During operations on the head under local anesthesia we have had the opportunity of observing which structures are sensitive to pain It has been found that all the tissues covering the cranium are pain sensitive, especially the arteries The cranium itself is insensitive, so that after the periosteum has been stripped the skull can be drilled or sawn through without the patient being aware of any sensation except the noise Of the intracranial structures most of the dura mater, all the pia arachnoid and the brain substance are insensitive The parts of the dura which are sensitive are those covering the base of the skull and the tentorium Pressure on the latter causes pain referred to the brow on the same side The falx, on the other hand, appears to be insensitive to pressure Although the dura is insensitive except at the base, the larger arteries are everywhere insensitive Thus crushing the middle meningeal artery causes pain Traction on the walls of the large venous sinuses and their main tributaries also causes pain and so does traction on the large arteries at the base of the brain Stimulation intracranially of the fifth, ninth, tenth and second cervical sensory nerves causes pain of appropriate distribution

Another source of information is the experimental production of headache The intravenous injection of 0 1 mg of histamine causes in most subjects headache after one minute, reaching its maximum half a minute later and passing off in about ten minutes It is of throbbing nature and generalized distribution Within twenty seconds there is flushing of the face with fall of blood pressure lasting less than a minute, so that the headache begins when the blood pressure is returning to normal It is known that histamine also causes dilatation of the arteries of the meninges and on the surface of the brain This in turn leads to increased volume of the intracranial contents and a rise in the cerebrospinal fluid pressure But not until this pressure has almost returned to normal does the headache begin It cannot therefore be due to increased intracranial pressure Further, it is relieved by raising the pressure either by compressing the jugular veins or by intracranial injection of isotonic solution of sodium chloride This suggests that the headache is due to stretching of the arterial walls

It has been shown that the headache of experimentally induced fever also can be temporarily relieved by artificially raising the pressure of the cerebrospinal fluid and that its onset is associated with increased amplitude of pulsation of the intracranial and intraspinal arteries It thus appears that the headache of fever is due to abnormal stretching of the arterial walls Since raising the intracranial pressure by injection of saline solution into the theca will relieve the headache, we may conclude that the arteries chiefly concerned are those within the skull

The headache of migraine is throbbing, like that due to histamine or fever The increased pulsation of the temporal artery on the same side led to observations which showed parallelism with the intensity of the headache Ligation of the temporal artery has produced freedom from pain Thus we are led to conclude that stretching of the arteries is the cause of the pain The headache of arterial hypertension appears to be due to the same cause and the headache of intracranial tumor to traction on or displacement of pain sensitive intracranial structures

BELGIUM

Sept 20, 1946

A Children's Hospital as a War Memorial

A Children's Hospital will be erected to perpetuate the memory of the allied soldiers who fell on the soil of Belgium for its liberation A committee has been formed in Brussels under the best auspices with the intention of raising funds for the construction of the memorial Rather than a monument of exclusively decorative nature, the committee has in mind an enduring and living monument dedicated to relieve the suffering of unfortunate children No institution in our country is prepared to admit children with chronic diseases or convalescents from acute diseases The institution which has been planned will be situated in Ostende facing the ocean On each of the stones of the edifice will be engraved the name of a soldier who died in Belgium The various pavilions will bear the names of army divisions that distinguished themselves in Belgium by deeds of valor

Centennial of Van Beneden

The centennial of Edouard Van Beneden was celebrated at the University of Liege Among those present were his children and other relatives, the civil authorities, delegations of the Royal Academy of Belgium the Royal Academy of Medicine, the staff of professors, numerous guests and students Van Beneden is memorialized especially for the creation of laboratories for everyday work and for research He and his brother in law, Van Pair, then professor of pathologic anatomy, purchased with their own money the microscopes It was only little by little that the government stepped in and extended the sphere of the laboratories to other faculties

Professor Winiwater recalled the brilliant scientific career of Van Beneden, particularly his work on embryology, in which he demonstrated that each mature sex cell encloses only half the number of chromosomes typical of the species The researches of Van Beneden justify classing him with the great biologists of all times and all countries

Tuberculosis Control

The efforts which private organizations devoted to the campaign against tuberculosis for nearly thirty years were coordinated in 1929 when the Belgian National Organization for Defense Against Tuberculosis was founded The executive committee, presided over by Dr Derscheid, meets every month to assure contact between the different sections of the national organization, to discuss projects, establish liaison with the government, make assignments and arrange the budget subsidies, and so on The three organizations, formerly independent, became sections of the national organization each intended for a special activity (1) general prophylaxis, (2) preservation of childhood and (3) treatment and cure

The essential aim of the league is to fight tuberculosis by means of the dispensary the program of which includes diagnosis, detection domiciliary prophylaxis and social assistance, 130 dispensaries with 225 physicians and 254 visiting nurses belong to it or are affiliated with it The preventoriums, because of their essentially prophylactic role, are connected with the league

In the preservation of childhood against tuberculosis the program is to raise and protect against infection the offspring of parents whose tuberculosis is contagious Its methods vary, since its care extends to children from birth to 14 years Its program being of a prophylactic nature, is closely allied to that of the League Against Tuberculosis

The section on treatment and cure devotes its efforts to the treatment and prophylactic isolation of patients suffering from the different forms of tuberculosis Thiry two sanatoriums belong to it or are affiliated with it They are situated in the country, on the coast, and even in foreign countries. Certain of these establishments have a social service for work outside the sanatorium, in the homes of the patients.

There are attached to the national organization a technical service competent to construct buildings suitable to the program, a publicity service on prophylaxsis, a service of publicity to stimulate the public to contribute funds to combat tuberculosis, a general accounting service and a medical library.

The organization of the national body is not as rigid as one might believe on the basis of this classification. Its different sections often combine their efforts. It is precisely in the role of coordinator that the national organization plays its most important part.

Medical Reserve Officers

A National Union of Medical Reserve Officers has been created under the presidency of Professor Debaisieux, who, in thanking his colleagues for responding to the appeal, emphasized that the new association ought to contribute to the organization of a superior health service. One of the principal aims of the association will be the creation of an atmosphere which will permit the health service of the army to function without friction. It is hoped that there will be close collaboration between military and civilian physicians, and it is desired that the faculties of medicine will collaborate in the instruction of the army health service.

BRAZIL

(From Our Regular Correspondent)

Rio de Janeiro, Sept. 17, 1946.

The Inter-American Congress of Medicine

In the presence of President Eurico G. Dutra, the first Inter-American Congress of Medicine, organized by the National Academy of Medicine, was inaugurated on September 7, the Brazilian Independence Day. Dr. Ernesto S. Campos, minister of health and professor at the University of São Paulo, presided at the opening session, addressing the several hundred physicians present as delegates from the American republics, to welcome them in the name of the Brazilian government. Dr. Campos reviewed the brilliant history of the old Imperial Academy of Medicine, founded one hundred and six years ago under the patronage of Pedro II, the second and last emperor of Brazil. It is the same academy which called the lively meeting closed two days ago, destined to mark a milestone in the future history of cooperation among the physicians of our continent. The second speaker of the inaugural evening was Dr. Antonio Austregesilo, professor emeritus at the University of Rio de Janeiro and president of the academy, who thanked the delegates for accepting the invitation of the Brazilian physicians to initiate this series of inter-American meetings of practitioners of all the specialties of medicine. In his address Dr. Austregesilo outlined the biographies of some great Brazilian physicians of the past—Alvarenga, Silva Lima, Torres Homem, Saboia, Rocha Faria, Francisco de Castro, Fajardo, Sodré, Oswaldo Cruz, Miguel Couto and Chagas. He emphasized the contributions of the physicians of the Americas, declaring that the Brazilian practitioners had invited their colleagues in order to have the opportunity of discussing the most pressing medical subjects and to acquire the knowledge they can bring and thus benefit from the professional interchange of the sister republics. After Dr. Austregesilo's speech, the heads of the foreign delegations addressed the congress, stressing the same spirit of brotherhood. Sir Alexander Fleming, a special guest of the Brazilian government, was chosen by the academy as honorary president of the congress. The meeting brought together such other leading figures of the medical profession of the Americas as Malcolm T. MacEachern of Chicago, Col. Charles O. Bruce of the Headquarters Army Ground Forces, Washington, D. C., James A. Shannon representing the U. S. Public Health Service, Roland Klemme of St. Louis, representing the American College of Surgeons, Tracy Putnam, Ardzroony Packchanian of the University of Texas, Howard E. Snyder of Winfield, Kan., George R. Cowgill of New Haven, Conn., George Hoskins of Boston, George Baehr of New York, David Speroni, professor emeritus at the University of Buenos Aires, Gregorio Alfaro, president of the Argentine Academy of Medicine, Nicolas Romano and Mariano Castex of the University of Buenos Aires, Cecilio Romaña of the University of Tucuman, Argentina, Salvador Mazza of the Argentine Mission of Studies of Regional Diseases, Francisco Forteza, minister of health of Uruguay, Juan C. Plá and Rodolfo Tallice of the University of Montevideo, Uruguay, and Francisco Garcia of Lima, Peru.

The congress was divided into twelve sections, which, with their respective chairmen, were concerned with hospital organization and administration (Ernesto S. Campos), medical and racial problems of immigration to the Americas (Antonio Austregesilo), war medicine and surgery (Col. E. Marques Porto), prevention and treatment of cancer (A. F. Costa Jr.), endemic diseases of the Americas (H. C. Souza Araujo), nutrition and vitaminology (Waldemar Berardinelli), endocrinology (Luis Capriglioni), treatment and prevention of tuberculosis (Affonso MacDowell), neuropsychiatry (Deolindo Couto), hygiene and public health (J. Barros Barreto), clinical medicine (Henrique Roxo) and clinical surgery (Alfredo Monteiro). Some of the subjects presented and discussed were organization and administration of American hospitals (Dr. MacEachern), conveniences and inconveniences of immigration to the countries of the Western Hemisphere (Dr. David Speroni, Argentina), cross breeding is favorable to Brazilians (Dr. Arthur Ramos, Brazil), military-medical importance of infectious hepatitis (Dr. Bruce), limitations of penicillin therapy (Sir Alexander Fleming), use of convalescent serums in the Argentine army (Dr. R. Bejarano), early diagnosis of neoplasms of the prostate (Dr. George T. Pack, New York), nonosteogenic bone tumors (Dr. Amadeu Fialho, Brazil), present state of the campaign against cancer in Rio de Janeiro (Dr. Costa), bronchial cancer and emphysema (Dr. Castex), possible existence of human cases of American trypanosomiasis in the United States (Dr. Packchanian), the problem of leprosy in the state of São Paulo (Dr. Nelson S. Campos, Brazil), leprolin, a new therapeutic agent against leprosy (Dr. Souza Araujo), the soya bean in the diet (Dr. Afranio do Amaral, Brazil), thyrotoxicosis (Dr. Hoskins), statistical results of the treatment of thyrotoxicosis (Dr. Plá), some important aspects of nutrition (Dr. Cowgill), clinical epidemiologic and social significance of primary infection and reinfection in tuberculosis (Dr. Fernando Gomez, Uruguay), collective and individual diagnosis of pulmonary tuberculosis (Dr. M. de Abreu, Brazil), mortality from tuberculosis in Brazil (Dr. R. Paula Souza, Brazil), subclinic forms of pulmonary tuberculosis (Dr. Estevam Somogyi, Bolivia), treatment of facial neuralgia (Dr. Klemme), modern aspects of psychosomatic medicine (Drs. Mauricio de Medeiros and Flavio de Souza, Brazil), the encephalorachial fluid in cerebral abscesses (Drs. Plá, Schiaffino and Morquio, Uruguay), professional training for the practice of psychosomatic medicine (Dr. J. Leme Lopes, Brazil), penicillin therapy of neurosyphilis (Sir Alexander Fleming), encephalomyelodysplasia (Dr. Austregesilo), sanitary indexes of Uruguay (Dr. R. Cappeletti), inter-American cooperation in the campaign against venereal diseases in the Western Hemisphere (Dr. L. Campos Mello, Brazil), the campaign against tuberculosis with limited financial resources (Dr. Barros Barreto), BCG immunization in tuberculosis control (Dr. G. Sayago, Argentina) and aseptic gastrointestinal surgery (Drs. Jorge Grey, Brazil, and Abilio Reis, Oakland, Calif.).

Correspondence

PSYCHIATRY IN WORLD WAR II

To the Editor:—I believe that all medical officers who served in both World War I and World War II will agree that the percentage of psychiatric cases developing in the second war was far greater than the percentage developing in the first. This at first glance is rather surprising, especially in view of the fact that during World War II *all* inductees had psychiatric examinations the purpose of which was to weed out the prepsychiatric cases. This was not true in World War I.

What then is the reason for the seeming deterioration of our citizen soldiery between the two wars? Certainly there could not have been any fundamental change in the psychosomatic makeup of our people in a generation. I venture to suggest the following reasons for the increase in psychiatric cases (exclusive of definitely psychotic cases) in World War II over World War I:

1. Too much public emphasis on psychiatric conditions.
2. A change in our political philosophy.

So much has been written in both the lay and the medical press about psychoneurosis, neurasthenia and psychiatric conditions in general that it has set every one to thinking about these conditions and undoubtedly many men have tried to use them as a means of escaping service. Induction board examinations revealed the fact that many men deliberately answered questions during their psychiatric examinations with a view to being rejected. They took their cues from other men previously rejected for psychiatric reasons. In combat and in theater of operations hospitals there were also obvious cases of attempts to secure evacuation by feigning psychiatric conditions, the knowledge of how to make the attempts being based on experiences gained from other cases which had been similarly evacuated. All of which would seem to indicate that the role of psychiatry in war has been played up too much in the newspapers and other places. Possibly medical men have talked too much about it in public utterances. The question arises as to whether we would not have been better off if the psychiatric examinations and the consequent stress on psychiatric conditions had been eliminated. In the case of inductees, if, as would seem on the surface, there was a smaller percentage of psychiatric cases during World War I than during World War II, would we not have been better off during the latter conflict simply to have eliminated the definitely psychotic cases? I am not prepared to say that we would have been, but certainly the results with methods used during World War II were far from satisfactory, and a consideration of their revamping is highly in order.

I believe that a change in our political philosophy has affected the patriotism and sense of duty of a great mass of our citizens. The great bulk of the youth who fought World War II reached maturity during an unusual period in our history. They grew up during a depression period when the government was handing out favors of all sorts to great masses of citizens. They had been accustomed to accepting something from their government. This was something entirely new in American history. Previously the soundest thought of the best citizens led them to believe that the citizen owed something to his country, and not the country to the individual. During World War II we found many "psychiatric" patients feeling, and openly declaring, after having been through one "island" campaign that they had "done their share." Certainly too many of our citizens did not properly feel their obligation to their country. (I am not referring to the congenital no-goods who do not have the fundamental basic stuff ever to feel the proper obligation to anything—family, friend or, least of all, country.) My experience with the rank and file of our soldiers leads me to believe that there is nothing wrong with them basically any more than there has ever been. I do believe, however, that a changing political philosophy has had its effect in producing epidemics of "psychoneurosis."

This communication is not written as a criticism of any one but simply to stimulate further thought on one of the most important medical problems that developed during the war. I think it is obvious to every one that we have not yet the answer. All psychiatrists with whom I have talked agree that this is true. They have worked hard and done their best, but psychiatry is a young subject. The specialty will undoubtedly benefit from the experiences of the war. Never before has it been put to such a great test on such a vast scale. It will probably take years of statistical study to evaluate the successes and the failures. In the meantime, one wonders whether we should continue our present method of induction examinations. Would it not be better to drop the psychiatric induction examination entirely, except for the elimination of the definitely psychotic cases by a careful study of the institutional records of the prospective inductees? Possibly a common sense evaluation of the men made by internists would be more satisfactory than the present psychiatric examination. A great deal of the problem is palpably that of internists. Should they not shoulder the major responsibility and call in skilled psychiatrists only in doubtful cases? This would eliminate part of the present trouble, namely that of spreading the skilled psychiatrists so thin as to make them virtually ineffective. I am not proposing this in any way except to provoke discussion. Who knows the answer? No one concerned should be interested in any solution but the one that would bring the greatest good to the country as a whole. Possibly psychiatry is still too young for the great task that has been placed upon it. Possibly not. Certainly the records so far call for at least a new tactical alinement.

AMOS R. KOONTZ, M.D., Baltimore.

TUBERCULOSIS

To the Editor:—In a communication to THE JOURNAL, September 28, Dr. Röder stated that in 1920 he had set forth the same views on apical predilection in adult tuberculosis that had been discussed as a new theory in an editorial in THE JOURNAL of July 13.

A comparison of his paper (*Wien. klin. Wchnschr.* **33**:646 [July 15] 1920) with that published by me (*Am. Rev. Tuberc.* **58**:297 [April] 1946) and discussed in the editorial shows that the two theories have nothing in common. On the basis of data only recently established and obtained by those who catheterized the right ventricle and pulmonic artery, it could be pointed out that arterial flow must cease in the apical zone when adults are sitting or standing quietly. I suggested that this permitted accumulation of toxins and prevented normal quantities of phagocytes and antibodies reaching the apical zones. Dr. Röder, on the basis of rather questionable data, chiefly from plant physiology, concluded that "the function of cells is proportional to the hydrostatic pressure" on them, that "with the constitutionally low pressure in the pulmonary capillaries a decrease in vitality must be encountered" and that "the important factor in predisposition is a low capillary pressure." No reference to any of these points was made in my paper, and Dr. Röder made no reference to blood flow, lymph flow, antibodies or phagocytes—the factors with which my paper was concerned. Both papers referred to facts in pathology and physiology which had been common knowledge since the late nineteenth century, but they drew entirely different conclusions from these facts.

The theory Dr. Röder offered had never been accepted, and for obvious reasons. A 4 per cent difference in absolute pressure on the cells is the maximal possible in the pulmonary capillaries—760 mm. of mercury at the apex and 760 mm. of mercury plus 30 mm. of mercury, the equivalent of 40 cm. of blood, at the base. If a lowering of the pressure by 4 per cent caused apical cells to be susceptible while those at the base were resistant, a change in altitude of 5,000 feet would make the entire lung far more susceptible than the apex at sea level. Yet the value of high altitude is generally conceded by those who treat tuberculosis.

Dr. Röder's "hydrostatic pressure on the cell theory" is not the same as that recently advanced to account for apical susceptibility. The recent theory is unproved, but it would be unfortunate to have it confused with older and discarded theories.

William Dock, M.D., New York.
Professor of Medicine, Long Island College of Medicine.

RADIUM POISONING

To the Editor:—In view of the devastating influence the atomic bomb might have on our civilization, I think the public should become acquainted with a study on radium poisoning which was made possible through financial aid from the American Medical Association. This was entitled "Experimental Radium Poisoning," by Maurice Rosenthal, M.D., and Edwin J. Grace, M.D., and dealt with bone marrow and lymph node changes in rabbits produced by oral administration of radium sulfate. It appeared in the *American Journal of the Medical Sciences* (**191**:607 [May] 1936).

Subsequent to the publication of this article there was an exhibit at the next annual session of the American Medical Association, dealing with the subject matter.

A therapeutic theory was held that it might be possible to produce, in an animal, deadly tissue damage from radioactive substance and then reverse this process and restore the animal to a healthy state. Ample evidence that this is impossible was given in the aforementioned article, which showed that the process is absolutely irreversible and that death invariably follows.

At the time this study was made, it was a very urgent clinical problem. One of the authors of this paper (E. J. G.) was interested in the approaching deaths of some patients suffering from radium poisoning, and at that time we were helpless to alter in any way this deadly phenomenon. It is well worth noting that now, ten years later, in spite of the great advances in medicine, especially in the field of antibiotics, nothing can be done to remove radioactive substances from body tissues.

The magnitude of the responsibility of the statesmen entrusted with the problems surrounding the atomic bomb demands very serious consideration of these clearly proved facts, and a plan of education should be instituted immediately to awaken the public to full realization that they cannot view indifferently this colossal missile of destruction.

Edwin J. Grace, M.D., Brooklyn.

PRIORITY FOR HYPERVENTILATION TEST

To the Editor:—In directing attention to the value of the hyperventilation test in my discussion of Lennox's article on Tridione in the Dec. 15, 1945 issue of The Journal, page 1074, it was my intention to establish Rosett's priority for having mentioned this test in 1918. The word Brain's should read Rosett's: the reference is *Brain* (**47**:293 [Aug.] 1924). I also directed attention to the previous use of caffeine in the treatment of petit mal seizures by Karger and others.

M. G. Peterman, M.D., Milwaukee.

BRITISH NATIONAL HEALTH INSURANCE

To the Editor:—It was with the greatest astonishment that I read in Dr. Edward Ochsner's evidence to the United States Senate Committee on Education and Labor (The Journal, August 3, p. 1150) his preposterous illustration of the methods of British National Health Insurance practice. He said "A prominent Chicago physician shortly before World War II visited a panel physician in England and went with him to see how he handled the waiting patient problem. As the doctors stepped into the waiting room the English physician said to the more than 40 patients seated there 'Will those of you who are troubled with headache please stand,' and 6 stood up. He then reached into his desk and took out six identical prescriptions and handed one to each of the 6 standing patients and dismissed them."

This is not the first time I have had occasion to protest against the misleading and inaccurate accounts given, evidently at second hand, by certain American doctors who are endeavoring to avert the introduction of any health insurance scheme into their own country by denouncing the British scheme. In the present instance Dr. Ochsner appears to have accepted as fact a story that must surely have passed round as a joke, and it is most deplorable that he should have repeated it in public as responsible evidence to a Senate committee. It is gross libel.

I can assure American readers that such methods are never adopted by British insurance practitioners and would indeed never be tolerated by patients or insurance committees. I challenge Dr. Ochsner to bring forward evidence to substantiate his allegations. If he cannot do so, I hope he will retract his statement, which has caused much distress to his British colleagues.

Charles Hill, Secretary,
British Medical Association.

[This letter was referred to Dr. Edward H. Ochsner, who replies:]

To the Editor:—I wish to say that the statement which I quoted before the Senate Committee on Education and Labor and which is criticized by the secretary of the British Medical Association was actually made by a then prominent Chicago physician.

Edward H. Ochsner, M.D., Chicago.

DISTRIBUTION OF MOSQUITOES

To the Editor:—I suppose you have already received some communications regarding the paragraph on page 236 of The Journal, issue of September 28. In this paragraph it is stated that "there are no Anopheles mosquitoes in Ceylon, but there are Culex and Aedes mosquitoes." This, of couse, is entirely untrue as regards Anopheles, since Ceylon has a very rich anopheline fauna, described in a number of excellent monographs (H. F. Carter and others). It is now well established that malaria in Ceylon is transmitted chiefly by Anopheles culicifacies.

Paul F. Russell, M.D., New York.

To the Editor:—On page 236 of The Journal, September 28, is a statement to the effect that there are no Anopheles mosquitoes in Ceylon.

A casual perusal of Fauna of British India, Diptera, volume IV Anophelini, by Christophers, reveals twenty-six species of Anopheles in Ceylon. There probably are more known by this time, because Christophers' book was published in 1933.

MEDICOLEGAL ABSTRACTS

Physician's Liability to Child for Injuries During Childbirth.—The plaintiff, an infant, by her father sued for injuries alleged to have resulted from the malpractice of the defendant physicians at the time of her birth. The case was heard on defendants' motion for summary judgment in the district court of the United States for the District of Columbia.

The question raised by the motion, said the court, is "whether an infant through its father and next friend has a right of action springing from the alleged fact that it was taken from its mother's womb through professional malpractice, with resultant consequences of a detrimental character." This is a novel question in this jurisdiction, the court continued, and judicial opinion, in those jurisdictions where it has been met, has held that at common law, in the absence of statute, prenatal injury affords no basis for an action in tort, in favor either of the child or of its personal representative. This conclusion is predicated, it appears, on the assumption that a child en ventre sa mere has no juridical existence and is so intimately united with its mother as to be a "part" of her and as a consequence is not to be regarded as a separate, distinct and individual entity. This doctrine was announced by Mr. Justice Holmes in the case of *Dietrich v. Inhabitants of Northamption,* 138 Mass. 14 (1884), which apparently has been relied on as dispositive and controlling ever since, except in those few cases in which recovery was barred on the theory of no contract and therefore no duty. In this opinion Justice Holmes said:

> Taking all the foregoing considerations into account, and further, that, as the unborn child was a part of the mother at the time of the injury, any damage to it which was not too remote to be recovered for at all was recoverable by her. . . .

Here, however, the court pointed out, we have a viable child —one capable of living outside the womb—and which has demonstrated its capacity to survive by surviving—are we to say now it has no locus standi in court or elsewhere? From the point of view of the civil law and the law of property, a child en ventre sa mere is regarded as a human being from the moment of conception—which it is in fact. Why a "part" of the mother under the law of negligence and a separate entity and person under the law of property and crime? Why a human being under the civil law and a nonentity under the common law? It has, if viable, its own bodily form and members, manifests all the anatomic characteristics of individuality, possesses its own circulatory, vascular and excretory systems and is capable now of being ushered into the visible world. In a Canadian case in which a woman seven months pregnant was descending from a tram, when, as the result of the negligence of the operator, she was thrown to the street and two months later gave birth to a child with club feet (*Montreal Tramways* v. *Leveille,* 1933, 4 Dom. L. R. 337) the court said:

> If a child after birth has no right of action for prenatal injuries, we have a wrong inflicted for which there is no remedy, for, although the father may be entitled to compensation for the loss he has incurred and the mother for what she has suffered, yet there is a residuum of injury for which compensation cannot be had save at the suit of the child. If a right of action be denied to the child it will be compelled, without any fault on its part, to go through life carrying the seal of another's fault and bearing a very heavy burden of infirmity and inconvenience without any compensation therefor. To my mind it is but natural justice that a child, if born alive and viable should be allowed to maintain an action in the courts for injuries wrongfully committed upon its person while in the womb of its mother.

The logic of this position, said the district court, is unassailable. The absence of precedent should afford no refuge to those who by their wrongful act, if such be proved, have invaded the right of an individual—employed as the defendants were in this case—to attend, in their professional capacities, both the mother and the child. And what right is more inherent, and more sacrosanct, than that of the individual in his possession and enjoyment of his life, his limbs and his body? That a right of action in cases of this character would lead to others brought in bad faith and might present insuperable difficulties of proof—a premise with which I do not agree—is no argument. The law is presumed to keep pace with the sciences and medical science certainly has made progress since 1884. The defendants' motion for summary judgment was therefore denied.—*Bonbrest v. Kotz, 65 F. Supp. 138 (Dist. of Col., 1946).*

Medical Motion Pictures

FILM REVIEW

Continuous Spinal Analgesia in Caesarean Section. By John C. Ullery, M.D., Philadelphia, with the aid of Norris W. Vaux, M.D., Clifford B. Lull, M.D., and Robert A. Hingson M.D., Surgeon, U. S. P. H. S. 16 mm. Color, silent, 1,008 feet (3 reels), showing time forty-two minutes. Produced in 19[illegible] at the Philadelphia Lying-In Hospital By Mervin W. La Rue. Procurable from Abbott Laboratories, North Chicago, Ill.

This film illustrates clearly the proper technic of continuous spinal analgesia in clinical cesarean section. The reactions of the average patient undergoing this procedure are also well illustrated. The photography is excellent. A few animal experiments are included showing the value of continuous spinal analgesia over the single injection technic. These would be of more value if captions were included explaining these views more clearly.

That the use of small divided doses of drugs for spinal analgesia is far superior to the single large injection technic is a well established fact. This film properly illustrates the value of this technic for cesarean section in the good risk patient. The choice of any spinal analgesia technic for cesarean section depends entirely on the condition of the patient, and this fact should be stressed by additional captions explaining the need for the adequate employment of fluids, plasma or blood to correct dehydration, exhaustion or shock from hemorrhage before any spinal analgesia can be attempted. Other definite contraindications to any spinal analgesia should also be stated. The value of oxygen administration during spinal analgesia, particularly when intercostal activity is decreased in addition to the decreased vital capacity of the woman at term, should be included. The blood pressure, pulse, respiration and general reaction of any patient under spinal analgesia need as careful watching as under any inhalation or intravenous anesthesia.

This film is of definite value in teaching students, anesthesiology residents and obstetricians the proper technic for continuous spinal analgesia for cesarean section. Additions to the text, as suggested, would increase the safety of this procedure.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal, Nov. 2, page 536.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part II.* Dec. 16-17. *Part III.* Boston, Nov. 19-21. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* Los Angeles, 2d week in April. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York.

American Board of Dermatology & Syphilology: *Oral.* Cleveland, Dec. 5-7. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

American Board of Neurological Surgery. Applications for examination will be accepted until Feb. 15. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago.

American Board of Ophthalmology: *Oral. All Groups. Parts I and II.* New York, June 1947. Final date for filing application is Dec. 1. Chicago, October 1947. Final date for filing application is March 1. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Me.

American Board of Pediatrics: Pittsburgh, Nov. 10-12, Boston, Dec. 13-15. Sec, Dr. Lee F. Hill, 3309 Forest Ave, Des Moines.

American Board of Urology: *Oral.* Chicago, February 1947. Final date for filing application is Nov. 15. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage *(6 cents if one and 18 cents if three periodicals are requested).* Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Role of Psychiatry in Children's Hospital Service: Account of Experiment in Integrating Psychiatry and Pediatrics in Inpatient Service. M. J. E. Senn.—p. 95.

Celiac Syndrome: Genetics of Cystic Fibrosis of Pancreas.—Cystic fibrosis of the pancreas was found to occur among siblings, twins and more distant relatives with a distribution which is compatible with the hypothesis that it is carried as a relatively infrequent hereditary trait. This conclusion was based on 48 cases in which the history of the sibling was known and on family pedigrees in 20 of these cases and also on 56 cases in the literature in which information as to siblings is given. Although the incidence among siblings approximates the 25 per cent expected of a mendelian recessive trait, the distribution of the cases in families suggests that the disease, although hereditary, requires more than one factor for its expression. This hypothetical factor is as yet unknown. The lesion in the pancreas is not a malformation in the true sense of the word but appears in the latter part of pregnancy. It probably results from an abnormality of the acinar secretion. A comparable disturbance is also found in the liver, the gallbladder and the intestine and possibly in other glands. The congenital intestinal obstruction often associated with pancreatic fibrosis is probably the result of failure of pancreatic function, with secondary changes in the meconium, often complicated by volvulus or congenital peritoneal adhesions. The latter two conditions frequently tend to distract attention from the meconium ileus. There is evidence that the pulmonary lesion begins after birth and is primarily the result of nutritional deficiency.

Laboratory Outbreak of Q Fever Caused by Balkan Grip Strain of Rickettsia Burneti. Commission on Acute Respiratory Diseases, Fort Bragg, North Carolina. J. H. Dingle and others.—p. 123.
*Identification of Q Fever in Panama. G. Cheney and W. A. Geib.—p. 158.
*Q Fever: Immunologic Comparison of Strains. N. H. Topping, C. C. Shepard and R. J. Huebner.—p. 173.

Agent of Balkan Grip a Strain of Rickettsia Burneti.—In May 1945 the Commission on Acute Respiratory Diseases received specimens of guinea pig blood containing a fever inducing agent from Caminopetros of the Institut Pasteur Hellenique. Caminopetros had isolated the agent by inoculating guinea pigs with the blood of a patient during an outbreak of respiratory disease in Athens. He had maintained it for about thirteen months by serial passages in guinea pigs. The only response of the animals to inoculation was fever. Blood taken from the animals during the febrile period contained the agent. The guinea pigs were susceptible to infection by the intramuscular, intracranial and intranasal routes and by direct injection into the lung. The observations of Caminopetros were confirmed by the commission. It was found that the agent grew well in embryonated hen's eggs, that it could be visualized as minute pleomorphic rods and that intracellular inclusions consisting of masses of the organisms occurred in the organs of the infected mice. Its pathogenicity for human beings was demonstrated by the development of 16 cases of laboratory infection. Confirmation of its identity as a strain of Rickettsia burneti was accomplished by means of serologic tests. Agglutination tests with *an antigen prepared from the Balkan grip strain of R. burneti* were used in studies of serums from outbreaks of Q fever and proved to be of value for the serologic diagnosis of the disease.

Immunologic Comparison of Strains of Q Fever.—Several strains of Q fever recently isolated from human cases of pneumonitis have been compared by Topping and his associates with one another and with known strains. The 6 strains used in these investigations were an Australian, an American, the Balkan grip agent, an agent isolated from the Fort Bragg laboratory outbreak, the Panama and the Henzerling strain isolated in Italy. It was found that complete reciprocal cross immunity occurs in guinea pigs. The immunologic relationships were studied by complement fixation and agglutinin absorption tests. These tests indicate similarity in immunologic specificity, although there were wide variations in the sensitivity of the antigens.

Pneumonitis in Rheumatic Fever.—Griffith and his associates define pneumonitis as a manifestation of rheumatic fever characterized by an inflammatory process of lung and pleura, *with an insidious onset, migrating consolidation and frequent* pleurisy with or without effusion. They observed pneumonitis in 119 of 1,046 rheumatic fever patients at a naval hospital. The pneumonitis is of three types according to its time of appearance in the rheumatic fever state: primary acute, secondary acute and subclinical. The diagnosis of pneumonitis of rheumatic origin is based entirely on the exclusion of the other types of pneumonia and the concomitant development of other manifestations of acute rheumatic fever. The laboratory aids are of little help in establishing the diagnosis. The rapid shift of areas of density in the roentgenogram, the rapid development of an effusion and the close adherence of the density to the bronchovascular markings are helpful in differentiating this condition. Pneumonitis is a serious manifestation of rheumatic fever activity.

Experimental and Clinical Evaluation of Synthetic Antihistaminic Drugs. S. Friedlaender.—p. 174.
*Comparative Study of Treatment of Tularemia with Immune Serum, Hyperimmune Serum and Streptomycin. L. Foshay.—p. 180.

Relation of Cardiac Enlargement to Hypertension in Glomerulonephritis.—Dean points out that the incidence of cardiac failure in glomerulonephritis is high, but opinions still vary about the cause of cardiac enlargement and cardiac failure. He reports 3 cases of acute glomerulonephritis with persistent enlargement of the heart associated with little or no hypertension and 3 cases of chronic glomerulonephritis with persistent hypertension but with little or no increase in heart size above the normal range of cardiothoracic ratio until shortly before death. He concludes that cardiac enlargement occurring in acute glomerulonephritis may persist for many years after the acute attack without evidence of significant hypertension at any time. Hypertension occurring in chronic glomerulonephritis may be present for many years without evidence of significant cardiac enlargement as determined clinically. Thus the height of the blood pressure and size of the heart as determined clinically in glomerulonephritis may be completely unrelated.

Immune Serum, Hyperimmune Serum and Streptomycin in Tularemia.—Comparisons based on records from 832 patients who received immune serum, 60 who received hyperimmune serum, 9 who received streptomycin and 542 who received only symptomatic treatment reveal that treatment of tularemia patients with immune serum before the end of the second week of disease induced significant reductions in mortality and in all aspects of morbidity. Greater reductions in morbidity were effected by treatment with hyperimmune serum or streptomycin. Of the agents studied only streptomycin and hyperimmune serum reduced the mean duration of disease to less than 2.5 months if treatment was given later than the second week. A comparative study of therapy to recovery intervals indicated that the nature of the disease imposed limits on the results obtainable by all forms of therapy. It indicates also that future comparisons should demonstrate a superior effectiveness of streptomycin in diminishing morbidity, and, since it is already shown to be a better agent for treatment of the desperately ill patient, that streptomycin will become the treatment of choice for tularemia.

Reconstruction of Floor of Orbit: Case. I. Givner.—p. 1010.

Streptomycin in Corneal Abscess Due to Escherichia Coli.—A man aged 54 had a severe corneal abscess caused by Escherichia coli. Owens reports that the abscess continued to progress in spite of intramuscular and local application of penicillin and the oral administration of sulfamerazine. When on the seventh hospital day streptomycin became available, the local use of penicillin was discontinued and two drops of a solution containing 500 standard units of streptomycin per cubic centimeter were instilled into the right eye every hour during the day and night. In forty-eight hours definite improvement was evident. On the fifteenth hospital day the systemic use of penicillin and sulfamerazine was discontinued. At the same time, through a mistake in dilution, the concentration of the streptomycin instilled into the conjunctival sac was increased to 10,000 standard units per cubic centimeter. This concentration was used for one week, after which the original dilution containing 500 standard units per cubic centimeter was used again. During this period of increased dosage the eye continued to improve steadily. The local use of streptomycin was continued for twenty-three days. At that time the corneal abscess had healed and was replaced by an epithelized leukoma.

Glomus Tumors (Angioneuromyomas): Clinical and Pathologic Report of Unusual Case. H. Jackson and Ruth Balkin.—p. 100.
Migratory Polyphlebitis. B. J. Ficarra.—p. 105.

Cholecystitis with Perforation.—Johnstone and Ostendorph found 32 instances of perforation of the gallbladder in a review of 12,000 consecutive routine necropsies done at the Los Angeles County Hospital, or approximately in 1 out of every 375 cases coming to necropsy. Its true incidence places the acutely diseased gallbladder high on the list of potentially fatal conditions as found in acute conditions within the abdomen. The dangers of so-called medical, or conservative, treatment of acute cholecystitis are emphasized. Once the diagnosis of acute cholecystitis is made, particularly in patients past 50, surgical intervention should take place as early as is consistent with adequate preparation. Interval cholecystectomy should be done in cases of recurrent chronic cholecystitis. Operation within forty-eight hours, employing cholecystectomy, is regarded as the effective means of lowering the mortality in acute cholecystitis. A mortality rate of 2.9 per cent for patients operated on within forty-eight hours compares favorably with the findings of other proponents of early operation. Early surgical intervention will lower the mortality from acute perforated cholecystitis just as surely as it has lowered the mortality from acute perforative appendicitis. The results in 105 cases of acute cholecystitis in which operation was performed show that mortality increases in proportion to the time of operative delay.

Blocking of Splanchnic Nerves.—De Sousa Pereira's report covers more than a thousand anesthetic blocks of the splanchnic nerves or of these nerves and the first lumbar sympathetic ganglion. Of the two routes of approach available for blocking the splanchnic nerves, the posterior approach was employed routinely in these investigations. When repeated anesthetic blocks were indicated, the needle was inserted not always at the same point but at different points in an area determined according to the topography of the splanchnic nerves and the first lumbar ganglion in relation to the skeleton. Encouraging results were obtained in the diagnosis and treatment of patients with cardiospasm, visceral pain and peptic ulcer. Single or repeated anesthetic blocks of the splanchnic nerves and first lumbar ganglion were tried in cases of paralytic ileus, megacolon and hypertension and in the postoperative period of abdominal operations as a method of diagnosis or treatment or as a test before splanchnicectomy. The results observed point out the clinical importance of anesthetic block of the splanchnic nerves and the first lumbar ganglion.

Interdependence of Cardiac Massage and Suck and Blow Resuscitation.—Reicher presents the results of studies supplementing those made by Thompson and Birnbaum, who have shown that alternating suction-inflation causes a reflex stimulus to respiration. A series of preliminary experiments were performed for the purpose of studying the lungventilator apparatus and to determine the value of suction and suck and blow in resuscitation. Reicher stresses that while the importance of combining cardiac massage with pulmonary ventilation in resuscitation have been demonstrated by Coryllos and by Thompson and Birnbaum, his experiments indicate that such a combination would frequently be inadequate if the pulmonary measures consisted in either pressure or suction used alone. The clinical implications are that suck and blow is the ventilation of choice when combined with cardiac massage. Both cardiac and respiratory stimulation should be used in asphyxia. Either alone is often ineffective. Unlike pressure, suction exerts a stimulatory effect on respiration, as indicated by the inspiratory gasp caused by a suction stroke. No such effect is noted with manual artificial respiration.

Id. 2. Studies on Normal Human Subjects—Effect of Repeated Short Exposures to Reduced Atmospheric Pressure. M. Clinton Jr., G. W. Thorn and Virginia D. Davenport.—p. 70.

Intestinal Obstruction.—Calihan and his associates investigated the clinical and necropsy records of the patients who have been treated surgically for acute mechanical intestinal obstruction of the small bowel at the Johns Hopkins Hospital for the ten year period 1936-1945. Complete obstruction was proved at operation in all cases as evidenced by distended loops above and collapsed loops below the site of the lesion. Of 204 cases reviewed 116 were simple mechanical obstructions, 27 were cases of volvulus, 35 were cases of internal hernia and 26 were cases of intussusception. There were 41 deaths, a mortality rate of 20 per cent. By excluding the cases in which death was not due directly to the intestinal obstruction (death due to cardiac failure, pneumonia, aspiration and death during spinal anesthesia) the corrected mortality rate was 15 per cent. Peritonitis was the greatest single cause of death accounting for 55 per cent of the fatalities. The authors cite the experimental work of Blain and Kennedy, in which massive doses of penicillin prolonged the lives of dogs with strangulated obstruction, and the studies of Blain, Kennedy, Calihan and Harkins, in which such dogs could be cured by resection at a period which was twice the survival time of control dogs not treated with penicillin. This would seem to indicate that penicillin may serve a similar useful purpose in strangulated intestinal obstructions in man. Penicillin is suggested as an aid to sound surgical therapy and not as another adjuvant with which to temporize in the treatment of acute mechanical intestinal obstruction.

*Massive Pulmonary Embolism: VIII. Based in Part on Study of 88 Fatal Cases. H. Neuhof and S. H. Klein.—p. 99.

Electroencephalogram in Subarachnoid Hemorrhage.—Greenstein and Strauss studied 29 cases of massive extravasation of blood into the subarachnoid space caused by rupture of a congenital or acquired arteriosclerotic aneurysmal dilatation of a cerebral vessel or provoked by trauma causing laceration of blood vessels. The diagnosis of subarachnoid hemorrhage was confirmed in all cases by the presence of blood in the spinal fluid. Eighteen patients presented only a meningeal syndrome clinically. Five patients showed focal as well as meningeal signs, 2 patients presented only focal signs and 4 patients presented neither focal nor meningeal signs. A correlation was found to exist between clinical cortical foci and focal abnormalities in the electroencephalograms. Neither the presence of blood in the spinal fluid nor the presence of meningeal symptoms bears any relation to the electroencephalogram. In all cases the degree of abnormality in the electroencephalogram showed a progressive diminution when repeated examinations were made at increasing intervals of time; this observation was not found as a rule in brain tumors, and it may offer an aid in the differential diagnosis between a bleeding cerebral tumor and a subarachnoid hemorrhage due to some other cause. No increase in the degree of electroencephalographic abnormality was noted in subsequent records, once the hemorrhage had ceased.

Massive Pulmonary Embolism.—Neuhof and Klein studied 88 fatal cases of massive pulmonary embolism. The factors producing death were obstruction of the pulmonary artery, asphyxia and heart failure. The fatal episode took place at any time during a medical illness (26 cases) or in the surgical postoperative period (62 cases). Of the 62 deaths in operative cases 21 occurred in the first week, 14 of these in the first few days. Only 26 were encountered in the second week, chiefly in the classic period of the eighth to the twelfth day. There was no dependable relationship between the degree, the location or the extent of the pulmonary embolus and the clinical picture. An operation always must be regarded as exploratory. A significant fact concerning the cases to be regarded as favorable for embolectomy was that the duration of life after the onset of symptoms was short in many. This is out of line with the protracted duration of life for which Trendelenburg's operation of pulmonary embolectomy has been advocated. Because of the criticisms of this operation the authors devised a transcardiac operation resting on the principle of noninterference with the pulmonary artery, the attempt being made to extract the thrombus by suction through an incision in the right ventricle. This operation was performed on an athlete aged 18 years. No thrombotic material was obtained from the main trunk of the pulmonary artery. The patient died fifteen minutes after the operation. Necropsy revealed that thrombi filled the right and left branches of the pulmonary artery. The operative procedure is simple and does not require a special team. The suction results in some measure of decompression of a right ventricle which is laboring unavailingly against the obstructing embolus and thus is a desirable feature, but the operation does not provide assurance that suction will engage the thrombus in the eye of the catheter or the end of a metal tube. Despite the fatal issue in the reported case further attempts to extract a pulmonary embolus through the right ventricle appear justified.

Streptomycin and Sulfadiazine in Influenzal Meningitis.—Nussbaum and his co-workers administered streptomycin concurrently with sulfadiazine to 3 infants aged 9 months, 16 months and 15 months in whom rapid recovery was obtained in the presence of severe influenzal infection of the meninges

The streptomycin was used both intrathecally and intramuscularly with no evidence of toxicity or undue reactions. Recoveries were complete in all 3 cases with no evidence of damage to the nervous system. Fifty thousand micrograms of streptomycin was given intrathecally daily until spinal fluid cultures were negative and clinical improvement was definite. Fifty thousand micrograms of streptomycin was given intramuscularly every three hours until a total of 3 Gm. was given in each case. Sulfadiazine in large doses was also given. Although this small series does not warrant definite conclusions, the dramatic influence of streptomycin is significant in patients under 2 years of age when prognosis is poor even with the use of the other antibiotics.

Tridione in Convulsive Disorders.—Clinical experience with tridione over a period of sixteen months in 75 patients with convulsive and related disorders has left Perlstein and Andelman with the impression that it is the most effective drug yet employed in the treatment of petit mal. Its anticonvulsant effect in the control of grand mal attacks is not as great as that of diphenylhydantoin sodium, phenobarbital or the bromides. It may occasionally be of value as an adjuvant in the control of major attacks not adequately controlled by other drugs. It is more effective in idiopathic than in organic epilepsy. It is of value in reducing the tension or rigidity of patients with cerebral palsy. Of these, athetoids are benefited more than spastic children. It may be of value in the temporary control of children with behavior disturbances. It may be of value in the control of the convulsions and respiratory spasms of tetanus when given intravenously, but it is of no particular value in chorea, parkinsonism or dystonia musculorum. Tridione is a safe drug to use, since no permanent deleterious effects, addiction or tolerance were noted. Toxic symptoms are usually mild and consist of photophobia, visual blurring, dizziness and nausea. They occur more commonly in adults than in children and disappear promptly when the drug is withdrawn. Sudden stopping of the drug in epilepsy does not result in status epilepticus. When used in combination it is more effective with phenobarbital than with diphenylhydantoin. Chronic alcoholism increases tolerance to the drug. Since it is least effective in lesions of the pyramidal system and more effective in certain conditions with extrapyramidal lesions, it is suggested that its site of action is probably in the midbrain and/or areas in the basal nuclei and/or on the cortical connecting tracts of these areas.

Streptomycin in Meningitis Due to Hemophilus Influenzae.—Weinstein treated 9 cases of purulent meningitis due to type B Hemophilus influenzae in 7 and to an untypable strain in 2 with streptomycin, and complete recovery occurred in 7 cases. The drug was given intramuscularly in doses ranging from 15,000 to 125,000 units every three hours and intrathecally in amounts varying from 10,000 to 25,000 units every twenty-four hours. One of the two fatalities showed complete absence of response to the streptomycin. The other death was due to an intercurrent Staphylococcus aureus bronchopneumonia which was not affected by penicillin. The blood and spinal fluid were cleared of the causative organism in twenty-four to forty-eight hours in all cases except the 2 due to atypical strains. No relapses or sequelae of the influenzal meningitis were observed in the patients who recovered. There were no toxic reactions attributable to streptomycin in the nervous, hemopoietic or urinary systems. Two of the patients receiving streptomycin developed infections, in 1 meningitis and in the other bronchopneumonia (both with bacteremia) due to Staphylococcus aureus after they were completely free from H. influenzae. Careful watch must be maintained for early signs of this type of involvement. It is suggested that penicillin be used as soon as Staphylococcus aureus becomes the predominant organism in the nasopharynx, even before the evidence of invasion is present. Penicillin and streptomycin could be administered together from the time treatment is started. Streptomycin appears to be the drug of choice in the treatment of meningitis due to Hemophilus influenzae.

Epidemiologic Aspects of Sensitivity to Histoplasmin and Tuberculin.—Furcolow and his associates cite several recent reports which have shown that there is a close relationship between sensitivity to histoplasmin and pulmonary calcification. Early in 1945 an extensive study was begun in Kansas City, Mo., to determine the significance of age, sex, race, residence and socioeconomic, familial and other factors in the sensitivity to histoplasmin. Histoplasmin and tuberculin skin tests and chest x-rays were made on over 17,000 persons. It was found that the percentage of positive histoplasmin reactors among white persons is slightly higher than among Negroes, higher among males than among females, and higher among nonlifetime residents than lifetime residents. The percentage of positive tuberculin reactors is three times higher among Negroes than among white persons. Little difference was observed between males and females and between lifetime and nonlifetime residents. The frequency of pulmonary calcification is over twice as high among reactors to histoplasmin alone as among reactors to tuberculin alone. The frequency of calcification among those who reacted to neither test was very low, equaling 2.6 per cent. Among those who reacted to either tuberculin or histoplasmin there is a considerable increase with age in the occurrence of calcification.

Penicillin in Gonorrhea.—Batchelor and his associates found that in 190 male and 55 female patients with gonorrhea a two injection scheme (twice 200,000 units) gave cure rates of 95.8 per cent and 90.9 per cent respectively. The dosage of penicillin used for gonorrheal infections may apparently delay the development of concomitant syphilis, and for this reason cases must be observed for at least six months. Failure of the two dose technic is not likely to produce resistance to penicillin. Routine irrigation is not necessary with penicillin treatment, but it may be tried if a urethral discharge persists for longer than three days. The two dose method, using saline solutions of sodium penicillin, is simple and easily applied.

Intrathecal Streptomycin in Meningitis.—Cairns and his co-workers administered streptomycin intrathecally in meningitis due to organisms which have been shown to be sensitive to streptomycin in vitro and in laboratory animals. Streptomycin was given intrathecally in solutions of from 10,000 to 20,000 units per cubic centimeter of isotonic solution of sodium chloride. Seven cases of meningitis were treated, and preliminary tests were made on 2 persons with inoperable malignant brain tumor. All 3 cases of pyocyaneus meningitis, the case of influenzal meningitis and the 2 cases of tuberculous meningitis were fatal. The case of achromobacterium meningitis was the only one in which recovery occurred. These cases indicate that treatment of advanced pyocyaneus meningitis with intrathecal streptomycin is not likely to be effective. In meningitis of recent onset the results of streptomycin are less discouraging. In the achromobacterium infection there was prompt subsidence of infection after use of streptomycin. In the infant with Hemophilus influenzae infection streptomycin treatment was followed by decrease in the number of the organisms and by clinical improvement. Cerebral vascular thrombosis then developed, and the infection recurred. Doses of 80,000 to 100,000 units once or twice daily are probably necessary, and in acutely ill patients such injections are not free from danger. Injections should be given slowly, and a safety valve should be provided in the form of an indwelling ventricular catheter draining at a pressure of 200 mm. of water. Some of the untoward reactions may have been the result of impurities.

Folic Acid in Pernicious Anemia.—Wilkinson and his associates employed folic acid in the treatment of 5 patients with pernicious anemia. The patients had the typical uncomplicated clinical picture of relapsing pernicious anemia—megalocytic anemia, megaloblastic marrow and achlorhydria but no signs of neurologic involvement. They were either untreated or had had no effective treatment for some months. There was a preliminary control period of at least two weeks during which no treatment was given, the reticulocyte count remained low and red cells and hemoglobin did not show a rise. The folic acid produced clinical remissions, with return of the marrows to normoblastic from megaloblastic states, and a restoration of blood counts toward normal levels. The achlorhydria persisted. These results show that synthetic folic acid will bring about remissions in patients with true addisonian pernicious anemia, and the responses seem in every way comparable to those obtained with liver extracts. The dosage used, 20 mg. by mouth daily at first, reduced to 10 mg. when the remission is well advanced, appears to be minimal, and some patients may need more. In 1 case parenteral administration was highly successful.

Penicillin Resistant Staphylococci in War Wounds.—The total number of patients investigated by North and his associates was 59, and from these 328 cultures of hemolytic staphylococci were isolated and tested. Analysis of the results shows that with regard to the penicillin fastness of staphylococci the cases fall into four groups: (1) those associated only with penicillin sensitive staphylococci in the wounds, 10 cases; (2) those in which penicillin resistant staphylococci replaced penicillin sensitive organisms during the period observed, 10 cases; (3) those associated only with penicillin resistant staphylococci in the wounds, 35 cases; (4) those in which penicillin resistant and penicillin sensitive strains alternated, 4 cases. Individual wounds were usually found to harbor staphylococci biochemically and serologically identical during the period of observation. After prolonged penicillin therapy the staphylococci recovered from the wound as judged by tests in vitro were almost invariably found to be penicillin resistant. This resistance in vitro did not affect the clinical response to penicillin. This depended on the nature of the wound and not on the behavior of the organism to penicillin in vitro. The term penicillin resistant staphylococci is a misnomer. It has been shown that they are not in themselves penicillin fast but elaborate a penicillinase which destroys penicillin. It seems unwise to conceive that in no circumstances would the presence of penicillin fast strains in lesions infected by staphylococci adversely affect the response to penicillin therapy. It has been shown that mice injected intraperitoneally with a certainly fatal dose of penicillinase producing staphylococci were not protected against death by large doses of penicillin, while other animals injected with a penicillin sensitive strain were saved.

Heart and Beriberi.—Casanova studied 100 cases of dry beriberi during an epidemic outbreak among Senegalese troops in Tunisia in 1940. The patients presented severe cardiac disorders resulting in death in inveterate cases of several months' duration, while in cases of wet beriberi the same cardiac manifestations but in a lesser degree, masked and occasionally attenuated, were amenable to treatment. There was a decided increase in pulse rate, with more than 100 beats per minute. Administration of digitalin increased the pulse rate and the discomfort of the patients, thus serving as a test for beriberi. Orthodiagrams revealed cardiac enlargement, particularly of the right portion, and violent throbs of the aorta and particularly of the pulmonary infundibulum. Electrocardiographic records showed a flattened P wave, prolongation of the PQ interval, an enlarged rapid QRS complex, a diphasic T wave, and in lead 3 a pronounced change of the ventricular wave of excitation, which took the form of a W or a capital M. These changes appeared to be irreversible even in early cases of dry beriberi in which the clinical signs, particularly the tachycardia, subsided as a result of vitamin therapy. In inveterate cases of dry beriberi the irreversible cellular changes affect the power of the myocardium to contract, causing an intracardiac disorder of conduction. Disturbances of tension and of rhythm may also be present which are manifested by a rather uniform clinical picture of cardiovascular erethism. An out of balance state of the glucides-vitamins relationship increased by excessive and prolonged action of the heart is to be considered the cause of these disturbances.

Serum Coagulation of Weltmann in Hepatobiliary Diseases. — Investigation of the Weltmann coagulation band on 70 persons who were apparently healthy revealed that only about 75 per cent of them presented a normal coagulation band. Studies on 13 patients with localized hepatic processes revealed considerable variations which only in certain cases could be ascribed to the primary disorder. In the diffuse hepatic processes there existed a tendency toward an enlargement of the coagulation band. This enlargement was most noticeable in 48 of 62 cases of hepatic cirrhosis. The fact that only 3 of the patients with hepatic cirrhosis had a shortened coagulation band and that in these there existed processes which would explain the shortening (Hodgkin's disease, pregnancy and fibrocaseous tuberculosis) indicates that in case of shortening of the coagulation band the diagnosis of hepatic cirrhosis should be doubted. In cholecystitis the results are extraordinarily variable and permit neither diagnostic nor prognostic conclusions. Weltmann's coagulation reaction is of no special value in hepatobiliary disorders and does not deserve being included in the laboratory study of these conditions.

New Treatment of Cerebral Edema.—Fuentes Besoaín used Schemm's method, which consists of an acidotic diet without chlorides and the administration of large quantities of fluid in the treatment of posttraumatic cerebral edema. He has used this treatment in more than 20 cases, of which 2 are reported. Consciousness returns more rapidly with this than with other treatments. Diuresis begins to increase from twelve to twenty-four hours after the treatment is begun and a decrease in headache and nausea accompanies the augmentation in diuresis. The psychologic condition of these patients is much better than when the water intake is limited. The treatment is usually continued for three or four days after the subjective symptoms have disappeared. Total recovery usually requires between six and twelve days.

Poliomyelitis in Pregnancy.—Horstmann and his associates state that of the 62 women aged between 20 and 34 with poliomyelitis treated in Blegdam Hospital during the 1944 poliomyelitis epidemic in Copenhagen 20 were pregnant; 15 were in the first half of the pregnancy. Three of these patients died in the acute stage of the disease, abortion occurred in 4 and the infant died shortly before or after delivery in 2 instances, while 11 children were born, all of whom developed normally after birth. Since the frequency of pregnancy in poliomyelitis here is about three times as high as might be expected from the birth rate of the population at the time, mere coincidence seems unlikely. No corresponding accumulation of cases of pregnancy in poliomyelitis has previously been observed at the hospital. No satisfactory explanation of the phenomenon was found. The increased incidence of poliomyelitis in adult age in recent years probably explains the susceptibility to poliomyelitis in pregnancy. In the 1943 poliomyelitis epidemic in Bleking 21 of the 53 women between 19 and 47 affected were pregnant (Dhunér, *Nord. Med.* **24**:2187, 1944).

Heredity of Osteochondrodystrophy: Silverskiöld's and Morquio's Syndromes.—From their survey of twenty-one families with osteochondrodystrophy reported in the literature Helweg-Larsen and Mørch conclude that there are two forms of the disorder, Morquio's syndrome, with skeletal changes localized especially in the vertebral column and inherited recessively, and Silverskiöld's syndrome, with skeletal changes mainly in the extremities and transmitted as a simple dominant character. This view is confirmed by the 12 cases described from three families with Morquio's syndrome and one family with Silverskiöld's syndrome. Isolated cases of Silverskiöld's syndrome perhaps originate through mutation.

Book Notices

Diseases of the Retina. By Herman Elwyn, M.D., Senior Assistant Surgeon, New York Eye and Ear Infirmary, New York. Cloth. Price, $10. Pp. 587, with 170 illustrations. Philadelphia & Toronto: Blakiston Company, 1946.

The author has attempted to present a complete work on retinal diseases, as none has been published since the work of Leber in 1916. The volume is divided into eight parts. While the illustrations are fairly complete, more colored illustrations would have added considerably to its value. Part 1 consists of 141 pages devoted to diseases of the retina resulting from disturbances in circulation. It is written in a logical style that should be fairly easily understood by students and practitioners. This section represents the most important part of the work, because without a thorough knowledge of its contents the remainder becomes meaningless. Considerable emphasis is placed on the various blood vessel changes frequently encountered, and the accompanying illustrations help to clarify the contents. Diseases of the retina resulting from vascular malformations follow. Parts 3 and 4, consisting of degenerative and inflammatory diseases of the retina, contain many microscopic illustrations tending to clarify the pathology involved. Such a presentation is lacking in most textbooks and tends to make this book considerably more valuable to the practitioner. The section on diseases of the retina leading to retinal detachments should have been more complete. There are too few colored illustrations present for essential teaching purposes, as most ophthalmologists are not too well versed on this subject. Modern methods of treatment are included but could have been more specific in details. The section on developmental anomalies of the retina is quite complete. The work as a whole will undoubtedly fill a breach in the present ophthalmologic literature and will be a valuable addition to the library of ophthalmologists.

Skin Diseases, Nutrition and Metabolism. By Erich Urbach, M.D., F.A.C.A., Associate in Dermatology, University of Pennsylvania, Philadelphia. With the collaboration of Edward B. LeWinn, B.S., M.D., F.A.C.P., Associate in Medicine, Jewish Hospital, Philadelphia. Fabrikoid. Price, $10. Pp. 634, with 266 illustrations. New York: Grune & Stratton, 1946.

The author has been a prodigious worker in the field of cutaneous metabolism, and the full fruit of his intense efforts are displayed in this volume. The book is divided into five parts. Part one is devoted to the biochemistry of the skin and the influence of nutrition on its physiology; part two deals with the nutritional causes of dermatoses, including a discussion of cutaneous diseases due to malnutrition, food allergy and alimentary infections and intoxications. Part three is concerned with cutaneous diseases caused by alterations of the gastrointestinal tract, the liver and pancreas. The fourth portion of the book discusses nutritional therapy, and the fifth consists of tables intended to help in prescribing the necessary diets.

This book represents a laudable effort to make available at one source a large number of references on the nutritional aspects of the skin (more than 1,300). One would wish that the author had selected them more carefully and considered them more critically. As they are, they seem to be gathered together with the idea of missing nothing. No serious attempt is made to evaluate or integrate them. The result is, therefore, more in the nature of a compilation. The style is somewhat discoursive, which may aid the cause of intimacy between the author and the reader.

Much of the material is a report of the author's own work. This is presented in such fashion that it is difficult to dissociate actually proved facts from theories. The great bulk of this presentation is not corroborated and yet is presented as approved. A great many ideas presented are contrary to what is accepted by most dermatologists. The average dermatologist finds few places in his practice where dietotherapy is really effective. A novice, however, perusing this book would gain the impression that diet is the major attack. Either dermatologists are wofully behind in this modality or the author is overenthusiastic. He has a passion for employing not only unorthodox concepts but also terms.

Finally, one asks who would profit from reading this book. The student and general practitioner would be overwhelmed and not be capable of separating the wheat from the chaff. It might help the average dermatologist to become more conscious of the nutritional aspects of his specialty. The work, however, would find its greatest usefulness for the dermatologist seriously interested in metabolism or the investigator in general by providing a large number of references. For this, the author is to be thanked. It has meant a tremendous amount of work and drudgery.

A History of Medicine. By Douglas Guthrie, M.D., F.R.C.S., F.R.S.E. With an introduction by Samuel C. Harvey, M.D., F.A.C.S., Wm. H. Carmalt Professor of Surgery, Yale University School of Medicine, New Haven, Connecticut. Fabrikoid. Price, $6. Pp. 448, with 72 plates. Philadelphia, London & Montreal: J. B. Lippincott Company, 1946.

By tradition the physician of bygone days was not only the healer but, together with the clergyman, the scholar of the European and American community; however, the tradition may represent a degree of wishful thinking. "Southern cooking isn't what it used to be—and never was!" might fit the situation. Be that as it may, certain it is that in this era of science—and *particularly in the past five years of speeded instruction in the* medical curriculum of our student body—the opportunity for the attainment of a broader cultural background has been restricted. With this in mind it might seem that the very minimum for a physician might include some knowledge of the development of his own profession. Under the circumstances it is gratifying to observe greater interest in the history of medicine, as evidenced by the expansion in the field of special journals, in monographs, both American and English, even in advertising mediums that appeal to the profession. This work of Guthrie's is a useful contribution in this direction. He presents a comprehensive but readable review of medical history that might be added to every physician's library with profit. Particularly impressive is the balance that he has been able to maintain throughout the book—in itself of real importance for a work of this character. For the modern period he has given impartial credit to the schools of the various countries. The role of the basic sciences, the development of the specialties, the technical achievements are all well integrated. The background of ancient practice is adequately treated, and the significance of the Renaissance for the rapid development of the true scientific interest that followed immediately in its wake provides a fascinating section. The appendix provides a short but useful bibliography and, together with a good index, makes reference easy. The illustrations are useful even if not quite up to the quality of the text or to prewar standards.

Off to a Good Start: A Handbook for Modern Parents. By Irma Simonton Black. Cloth. Price, $2.50. Pp. 256, with illustrations by Lydia Cooley. New York: Harcourt, Brace and Company, 1946.

This is a nontechnical handbook about the day to day problems which confront the modern parents of young children. The excellent advice it contains is based on the now well established standards of normal behavior. The author's vast experience and excellent method of imparting her acquired knowledge in this field make it easy for the reader to follow the widening circle of the child's interests and activities. Part I, on the child himself and his habits, deals with his training and growth. Part II, on the child and his family, takes up discipline and punishment. Part III, on relation with other people, analyzes different types of children. Part IV, on adventuring in a larger world, deals with new experiences. Part V, on intellectual growth, takes up the methods of acquiring information, creative play and language. The book is written so that parents with at least a high school education can understand and execute the wealth of advice the author imparts.

Tablas del valor vitaminico de productos vegetales comestibles. Ministerio del Interior, Dirección nacional de salud pública, publicaciones del Instituto nacional de la nutrición, director general Prof. Dr. Pedro Escudero. Paper. Price, 2.50 pesos. Pp. 53. Buenos Aires: Instituto nacional de la nutrición, 1945.

This book is a compilation of tabulated data showing the principal vitamin values for both fruits and vegetables. Methods of analysis are described.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

POOLED BLOOD FOR BLOOD BANKS

To the Editor:—Please discuss the use of pooled whole blood in a blood bank. I contemplate establishing a blood bank and understand that pooled whole blood without the necessity of typing or cross matching is the newest accepted procedure. Marvin M. Harris, Ph.D., Macon, Ga.

Answer.—If the term pooled whole blood is meant to indicate a mixture of blood of the various groups, it may be said that this procedure is absolutely contraindicated in preparation for transfusion. Pooling of two or more different groups would result in agglutination and/or hemolysis of at least one of the bloods. For example, mixing of group O and group A blood would result in action of the anti-A antibodies of the O blood on the A cells.

Pooled lots of group O have been used for "universal donor" transfusions (Orr, W. H.: Pooling of Whole Type O Blood, *Hosp. Corps Quart.* **18**:53 [Oct.] 1945). The purpose of such pooling was to dilute the occasional group O blood with a high anti-A or anti-B agglutinin content with those which had a low or average agglutinin content. Thus there would be less danger of hemolysis or agglutination of the recipient's cells when the pooled group O blood was administered to patients of groups A, B or AB.

The practice of pooling group O blood for transfusion to recipients to all groups is not recommended in the operation of hospital blood banks because the process of pooling is apt to traumatize the cells or permit contamination.

The danger of administering high titer group O blood to an A, B or AB recipient may be avoided by dividing all group O donor bloods into two groups (McGraw, J. J.; Vaubel, E. K.; Reichel, John, Jr., and Elliott, John: Complications of Blood Transfusion, *Surg. Clin. North America* **25**:1024 [Oct.] 1945). Those with a relatively low titer may be used for recipients of group A, B or AB. Those with a higher titer may be used exclusively for group O recipients or converted to low titer bloods by the addition of Witebsky's A and B substances (prepared by Eli Lilly & Co.). "High titer" group O bloods may be separated from those with a comparatively low titer by testing a single dilution of the O serum against A and B cells. If the diluted serum agglutinates either A or B cells, it should be considered as having a high titer and therefore should not be administered to A, B or AB recipients.

It is difficult to recommend the exact dilution to be used, since various laboratories will differ in the interpretation of the tests. A technic should be chosen which results in labeling about 25 per cent of all O bloods as having a high titer. If the 25 per cent with the highest titers are used for O recipients it will be safe to use the other 75 per cent for A, B and AB recipients. Group O bloods which have a low or average content of anti-A and anti-B agglutinins may be used for patients of all groups without fear of a serious hemolytic reaction as a result of action of these agglutinins on the patients' cells. However, every transfusion should be preceded by a cross matching test except in the gravest emergency. In such cases low titer group O blood may be used. If the recipient is a woman or a man who has received previous transfusions the low titer group O blood should be Rh negative. Cross matching should be performed to check on errors in blood grouping and to check on the presence of atypical agglutinins in the patient's serum.

The use of two drops of the donor's citrated or oxalated whole blood and one drop of the recipient's inactivated serum spread thinly on a warm plate is recommended for the cross matching test. Diamond has shown that this test will detect anti-Rh agglutinins even in the presence of blocking antibody. It will also detect A B O incompatibilities.

REMOVAL OF MUST ODOR FROM BOOKS

To the Editor:—How can one get the smell of must out of papers and books? Don H. Duffie, M.D., Central Lake, Mich.

Answer.—The smell of must in books and papers arises from the growth of molds. There is no satisfactory way of inhibiting mold growth in a humid atmosphere. The only way is to keep books and papers in a dry place.

BRISTLE WORM IN STOOL

To the Editor:—The stool specimen of a patient with chronic enterocolitis of four months' duration showed the presence of a water crustacean identified as a "bristle worm." This form when found in well water is evidence of pollution by surface water. What is the suggested treatment after all conservative measures have proved futile? W. F. Giegerich, M.D., Atlantic, Iowa.

Answer.—The term "bristle worm" has been used in referring to one of the segmented worms of the class Chaetopoda. It may be that this is the worm in question. Regardless of the exact identity of the worm, the possibility that it represents a contamination of the feces occurring after the stool was passed should first be excluded. Such contamination is not uncommon and consequently organisms which do not come from the patient's gastrointestinal tract may at times be found in stool specimens submitted for examination.

When such worms as the bristle worm are ingested, it is not known that they can survive in the human gastrointestinal tract and furthermore, if they can, that they are capable of giving rise to symptoms of any kind including those of chronic enterocolitis. In the presence of diarrhea, with rapid passage of the gastrointestinal contents, ingested solids may at times be easily recognizable in the feces. So even though it can be conclusively demonstrated that the worms are both ingested and excreted by the patient, this does not constitute adequate evidence that the worms are the cause of the patient's symptoms.

Known causes of chronic enterocolitis must first be excluded, and, since there are many, numerous examinations may be necessary before a diagnosis is possible, including repeated examinations of the stools for parasites and bacteria of known pathogenicity, various blood agglutination tests, proctoscopy and x-ray examinations of the gastrointestinal tract, to mention only a few.

Insufficient information concerning the patient is given to permit more than superficial speculation as to the cause of the chronic enterocolitis. In view of these considerations there is no basis on which to recommend therapy. Certainly all measures usually employed in the treatment of parasitic infestations of the gastrointestinal tract seem contraindicated unless it is definitely known that the patient does not have any one of a number of possible infections or diseases. The drugs employed for the purpose are not uncommonly toxic even to those with a presumably intact gastrointestinal tract. In the patient under question the beneficial results that could be expected from such therapy seem so slight that the risks involved are not justified.

OBESITY, HYPOGONADISM, UNDESCENDED TESTES

To the Editor:—A boy aged 8 years has hypopituitarism. He weighs 94 pounds (42.6 Kg.) and has girdle type obesity and all the classic symptoms, including tiny genitalia and undescended testes. Roentgenograms show the sella turcica to be about one-third the normal size. He has been "shot" with about everything, including pituitary extract, anterior and posterior extracts of the gland and male sex hormone and has taken all kinds of tablets by mouth. Are there any recent developments in the treatment of such cases? W. B. Chapman, M.D., Joplin, Mo.

Answer.—Three problems are presented by the case described in the query: obesity, hypogonadism and undescended testes. The same material may be used for the undescended testes and the hypogonadism. The patient may be given 500 international units of chorionic gonadotropin by intramuscular injection three times a week. This treatment should be continued until moderate growth of the genitalia occurs. If the treatment is ineffective, testosterone propionate may be given in a dose of 25 mg. three times a week, and once again the treatment should be continued until moderate growth of the genitalia occurs. Occasionally when both testes are intra-abdominal they do not respond to chorionic gonadotropin. If testicular descent does not take place after the genitalia have shown moderate growth, operative procedures should be carried out at once for the correction of the cryptorchism. After the testes have been brought into the scrotum either by glandular therapy alone or by the combined use of glandular therapy and operative procedures, glandular therapy should be discontinued until the patient is about 11 years old. He is a little too young to undergo puberty. At the age of 11 chorionic gonadotropin or testosterone propionate, if chorionic gonadotropin is ineffective, may be started and continued until epiphysial closure takes place. It is impossible to state at this time whether or not some treatment of this type will be necessary for the remainder of the patient's life. He should be placed on a suitable reducing diet immediately to reduce his weight to the desired level, and thereafter it should be held there. Desiccated thyroid may be of aid as an adjunct in weight reduction but will have little or no effect on the genital growth and on the undescended testes.

DUST HAZARDS IN MANUFACTURE OF MANIKINS

To the Editor:—Are there any occupational hazards in the manufacture of display manikins? These are molded from plaster of paris, sandpapered, sprayed with lacquer paint and then packed in shredded newspaper. The atmosphere is usually filled with a mixture of plaster of paris dust, paint and newspaper dust. Would a person with sinusitis and severe chronic bronchitis suffer an extra risk? Should any precautions be taken?

M.D., New York.

ANSWER.—This situation introduces a number of theoretical opportunities for small injuries. Lacquers contain acetates, the vapors of which may be mildly irritating to any person. Sandpaper depends on silica for its abrasive action. If the silica dust created is extensive and the exposure prolonged, the possibility of silicosis exists. Dust counts will afford some index of the total dust present, but special procedures will be required to establish the proportion of free silica. Plaster of paris (calcium sulfate) is rated only as a nuisance dust, but gross amounts of any nuisance dust are objectionable and may, on a mechanical basis if not chemical, be disturbing to workers, especially those with nasal disorders. The quantity of dust from packing with shredded paper is likely to be negligible. In larger operations such as the press rooms of daily papers, complaints arise of alleged irritation from paper dust and ink. However, serious cases are not known. In general any worker with the disease states mentioned in the query would be more responsive to these mild irritants than a healthy worker. For protection due consideration should be directed to the feasibility of exhaust systems, either general or local, depending on the quantities of dusts or vapors present. Nuisance dust respirators which are readily available will bar coarse dusts such as from paper but cannot be relied on as protection against either vapors or silica dust.

EFFECT OF FLUORIDE IN FLAC TABLET

To the Editor:—A tablet named Flac, manufactured by the Flac Company, Newark, N. J., contains calcium (or CaO) 0.113 Gm., phosphate 0.153 Gm., fluoride 0.00012 and vitamin D 70 U. S. P. units. Several patients have asked whether the fluoride contents of this tablet will affect the sex glands and cause sterility.

F. J. DeCesare, M.D., Roselle Park, N. J.

ANSWER.—Atrophic changes may be produced in the testes and perhaps in the ovaries of rats by continued feeding with fluoride at the rate of 20 to 30 mg. of fluorine per kilogram of body weight daily. For a 70 Kg. man this would amount to a daily intake of 1,400 to 2,100 mg., at least twelve thousand times the 0.12 mg. said to be contained in a Flac tablet. Sterility occurs only as the result of advanced inanition. It would be more reasonable to fear mottling of the tooth enamel, which may occur in children with a daily fluorine intake of about 2.5 mg., about twenty times the amount in the Flac tablet. The normal daily intake of fluorine varies with the water supply but averages about 2 mg., or fifteen times the amount in the Flac tablet.

ARTERIOSCLEROSIS AND CALCULUS FROM CALCIUM AND PHOSPHORUS ADMINISTRATION

To the Editor:—Wafers of dicalcium phosphate 9 grains (0.6 Gm.) and calcium gluconate 6 grains (0.4 Gm.) with viosterol one to three times daily are often effective in reducing nervous irritability following alcoholism, pregnancy, infectious diseases or excessive fatigue. Will such continued calcium feeding increase the possibility of forming renal, ureteral or cystic calculi or arteriosclerosis?

Edward J. Kempf, M.D., Long Island, N. Y.

ANSWER.—There is no evidence to show that administration of the amounts of calcium and phosphorus mentioned in the query, in conjunction with normal requirements of vitamin D, would contribute to the formation of calcium deposits in a healthy urinary tract or blood vessels. The increased calcium and phosphorus content of the urine which such medication would cause may contribute to stone formation if predisposing local factors, such as stasis and infection, are present in the urinary tract. While it has never been proved that an arteriosclerotic process can be hastened by a moderate intake of vitamin D and calcium salts, yet, without a specific indication, it seems unwise to increase the calcium and vitamin D intake of elderly persons above that present in an adequate diet.

TOXICITY OF FLUORINE AND HYDROFLUORIC ACID

To the Editor:—Is it possible for fluorine gas to develop a complete anuria and destruction of one kidney necessitating the removal of the kidney?

M.D., Kansas.

ANSWER.—According to Largent, fluorine gas remains rarely as fluorine gas per se on exposure to air. With water vapor present, hydrofluoric acid is formed readily. Recently, however, fluorine has been made available commercially for research purposes. No one as yet seems to know exactly how the specific toxic reaction of fluorides is produced. Externally, fluorine is an irritant. Presumably the effects mentioned would be considered in respect to chronic poisoning, since only rarely does anuria occur in acute poisoning. In chronic poisoning anemia and gastrointestinal and neurologic reactions may be found. Albuminuria is not uncommon, but severe renal damage, as mentioned in the query, has not been reported even in the series on fluorine intoxication by Kaj Roholm. Although mild degrees of renal damage may occur as part of the picture of chronic (or even acute) poisoning, no such severe (infected secondarily?) proved fluoride renal damage necessitating surgical intervention has occurred. If it is possible, detailed chemical studies for fluorides as well as pathologic studies of the involved kidney should be done. These should be correlated with fluoride excretions studies of the individual.

STANDARDIZATION OF ANDROGENS

To the Editor:—Some companies market the male sex hormone in capon units per cubic centimeter. How does this compare in strength with testosterone propionate? For example, how many milligrams of testosterone equal 1 capon unit?

A. C. Scott, M.D., Evansville, Ill.

ANSWER.—The international unit for androgenic activity is equivalent to 0.1 mg. of crystalline androsterone. One capon unit of activity is equivalent to 1.5 international units. One mg. of testosterone propionate contains approximately 50 international units, or about 32 capon units.

CIRCUMCISION OF NEWBORN

To the Editor:—An increasing number of obstetricians are circumcising newborn infants at the time of delivery. Is this a wise procedure? How great is the danger of hemorrhage?

M.D., Florida.

ANSWER.—Circumcision of the newborn infant is a wise procedure for the reason that it will prevent the occurrence of many penile disturbances in later life such as phimosis, paraphimosis and persistent balanoposthitis.

There is little danger of hemorrhage in the newborn unless the baby is suffering from some blood dyscrasia.

FLAT FEET IN CHILDREN

To the Editor:—The answer to the query on "Arch Supports for Flat Foot in Children" appearing in The Journal, Aug. 10, 1946, page 1254, is far too dogmatic. It would be fairer to say that there is one group of orthopedic surgeons which feels as does the expert who answered the query. It would be still fairer to say that there is another group of competent orthopedic surgeons who feel entirely differently. I am one of the latter group. I feel that a pronated weak foot in a youngster definitely requires support, as the absence of support will result in a deformity of the tarsal bones as the child develops, since the bones will grow in the malposition of pronation. I still feel that the youngster with a weak pronated foot would definitely improve with exercise. However, any one who has ever handled infants and growing children knows how difficult it is to have them do exercises throughout a day. An occasional exercise morning and night for just a few minutes is of value only in giving mother gray hair and a sense of satisfaction that she is doing something for her child.

Harold Lefkoe, M.D., Philadelphia.

FRIGIDITY

To the Editor:—As a general practitioner interested in psychosomatic medicine, I wish to add several comments to the much discussed problem of frigidity. The psychologic aspect is more important than any other factor, and for this reason both surgery and endocrine therapy have been unsuccessful. This is a common problem, and many patients seen by the general practitioner can be treated successfully by him. The average patient is reluctant to be referred to the psychiatrist or the psychoanalyst. A complete social history is obtained, with particular reference to the psychosexual development. With this the attitudes, feelings, incorrect and inadequate information and traumatic experiences are often uncovered. Then in several brief sessions of psychotherapy the patient gains insight into her problem and the frigidity disappears,

MATERNAL WELFARE AND THE NEGRO

Chairman's Address

PHILIP F. WILLIAMS, M.D.
Philadelphia

Many types of agencies are concerned today with the problems of pregnancy. Medical, nursing, hospital, public health, educational and governmental bodies, stimulated by reviews of the vital statistics of reproduction, have interested themselves in improving maternal welfare. This term implies the full use of all facilities for the promotion of adequate maternity care. During the past decade great strides have been made in this direction.

An early educational effort by the government, the Sheppard-Towner Maternity and Infancy Act, passed by Congress in 1921 and administered by the Children's Bureau from 1922 to 1929, established the principle of grants-in-aid for federal and state cooperation in maternal welfare. The Social Security Act of 1935, which became effective in 1936, greatly expanded the educational features of the earlier act and made prenatal clinics and public health nursing and nutrition services more readily available to a larger proportion of pregnant women. Under the Sheppard-Towner Act $1,900,000 was made available to the states each year. Under the Social Security Act the annual amount is $5,820,000.

The continued provisions of the Social Security Act have been overshadowed by the wartime Emergency Maternity and Infant Care program which has provided free care for the wives and newborn infants of men in the lower pay grades of the military service. The sum allotted by Congress for this program for the fiscal year 1945 was $42,800,000.

In recent months legislative proposals have been advanced to make complete maternity care at federal expense or through compulsory health insurance available to all women electing such benefits.

During these same years the medical profession has extended maternal welfare by emphasizing better antepartum care, by stressing the value of conservatism in obstetric surgery, by aiding in the revision of hospital regulations regarding consultations, operative privileges and obstetric facilities, l [illegible] ate education and training and by [illegible] have also given instructions in maternity hygiene to their patients, the husbands and the general public. Through maternal welfare committees they have carefully reviewed individual maternal deaths and endeavored to discover and eliminate the conditions responsible for those that were deemed avoidable. Such committees have acted as advisers to local, state and federal health agencies. Some competent observers state that the reduction in maternal mortality in this country in recent years has been due largely to these activities of the medical profession; the profession assuredly has had an important part in the reduction.

Outstanding among the many individual and organized efforts in this field must also be mentioned the work of the American Committee on Maternal Welfare, the American College of Surgeons, and the American Board of Obstetrics and Gynecology. Notable, too, have been the contributions of the Maternity Center Association, the National Health Council for Mothers and Babies, the American Hospital Association and the American Public Health Association.

The results of these intensive, expensive and combined professional and lay efforts toward improving maternal welfare should be reflected in the trend of the puerperal death rate. Prior to 1933, however, assessment has been difficult; from year to year the Birth Registration Area established in 1915 expanded as states were added, and it was only in 1933 that statistics on births and deaths became available for the entire United States. Some progress was effected during these years, but even under the Sheppard-Towner Act the evidence was discouraging. In the group of states in the Birth Registration Area each year of the period 1921 to 1929, the rates for 1921 and 1929 were, respectively, 67 and 64 per 10,000 live births,[1] and the total decrease during these eight years of federal and state cooperation under the Sheppard-Towner educational program amounted to only 4.5 per cent.

In 1933, when the entire continental United States came to be included in the Birth Registration Area, the rate was 62 per 10,000 live births; in 1935 it was 58. Each year since then it has dropped progressively. In 1943, the latest year for which I have United States Bureau of Census Reports, it was 25. The decrease since 1933 amounts to 60 per cent; that during the eight years of operation under the Social Security Act amounts to 57 per cent.

This reduction must be regarded as an outstanding achievement in public health. It may be attributed to the interest and participation of professional and lay workers, the implementation of their efforts in education and maternity care by federal and state funds, the advances in obstetric practice, the newer treatments against infection and the increasing maternity hospitalization, especially in rural communities.

Although the reduction in the puerperal death rate is gratifying, careful analysis of the index shows a definite disparity between the rates for the white and the Negro mothers. Year after year the Negro puer-

---

Read before the Section on Obstetrics and Gynecology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

[1] Vital Statistics, United States Bureau of the Census, and Reports of State and Municipal Bureaus of Vital Statistics.

peral death rate has been double or more than double the rate for white mothers. This situation merits serious consideration.

Negroes constitute 10 per cent of the population of the United States. They are more numerous in the South, it is true, yet their ratio to the white population in many northern communities is so high that the problems of the Negro, especially those of maternity care, are of considerable importance. In connection with this situation former Governor Jones of Louisiana wrote recently, in *Liberty* magazine, that the migration of the Negro northward due to the war and the mechanization of agriculture had been over 100,000 annually since 1940. He quoted Dr. Edwin R. Embree, president of the Julius Rosenwald Fund, an authority on the Negro, to the effect that in fifteen years the ratio of Negroes in the North and in the South may be reversed, with 9 million in the North and 4 million remaining in the South. This gigantic problem of millions of Negroes voluntarily displaced and thrust on sections unfamiliar with the peculiar problems which inevitably arise holds for the obstetrician and for others the need for much forethought and planning.

In 1943 in the United States 1 infant out of every 9 born alive was Negro. In the southern states 1 infant out of every 4 was a Negro. In New York city and Philadelphia with large and increasing Negro populations, the 1938 births to nonwhite races comprised, respectively, 7 and 16 per cent of all births; in 1944 they comprised, respectively, 9 and 18 per cent. In other northern cities which are large industrial centers the 1943 percentages varied from 4 for Boston to 16 for St. Louis. Negro births in California more than trebled from 1939 to 1944; there were 1,741 in 1939, and 5,589 in 1944.[1]

A disproportionately high maternal mortality rate is evidenced for the Negro population throughout the period of record. In 1933 the United States rate for the Negro was 100 as compared with 56 for the white. In 1935, the year before the Social Security Act became effective, the rate for the Negro race was 95, that for the white was 53. During the years of operation under this act substantial decreases occurred in the rates for both races. The 1943 rate for the Negro was 51, that for the white was 21. The decrease amounts to 46 per cent for the Negro, 60 per cent for the white. The 1943 rate for the Negro is almost two and a half times that for the white; it is the rate that prevailed for the white in 1936.[1]

The excess of the Negro rate over the white rate appears in both the North and the South; it is appreciable in every state that has a considerable number of Negro births. In Georgia and in Mississippi in 1931 the Negro puerperal death rate exceeded the white by 45 per cent; in 1943 the excess of the nonwhite over the white amounted to 74 per cent in Georgia and 100 per cent in Mississippi. In Michigan, where over 90 per cent of the nonwhite births occur in cities and largely in Detroit, the nonwhite puerperal death rate in 1943 was 159 per cent higher than the white. In New Jersey in 1943 the rate for the nonwhite was 138 per cent higher than the rate for the white.[1]

Why should the Negro puerperal death rate remain double or more than double the white rate and show, in comparison, a ten year lag in its reduction? Is it because of some inherent difference of a constitutional nature, a biologic inheritance? Are the obstetric problems of the Negro essentially unlike those of the white? Does the cause lie in the contrasting situations of economy, education or social heritage?

The racial differences of the Negro compared with the white in reaction to diseases, both as to incidence and pathology, according to Raymond Pearl,[2] are so great that they should be taken into account in planning health programs. Although, as Pearl remarked, the Negro may enjoy a greater biologic fitness than the white in some respects, in others he is apparently distinctly less well adapted to the general environment in which he must live and have his being. On the other hand, Rudolph Matas,[3] writing fifty years ago on the Surgical Peculiarities of the Negro, discounted any inherent ethnic predispositions but felt that such apparent predispositions were due to conditions of environment. As recently as this year, Eastman[4] writes that he does not consider that the Negro woman faces any especial or intrinsic hazard in maternity because of her race. He believes that if Negroes had adequate medical attention it might well turn out that there were no inherent differences between the two races.

There is a greater incidence of hypertensive disease in the Negro. It occurs three times as frequently as in the white and appears earlier in the Negro woman. Nephrosclerosis and hypertensive cardiac disease are more frequent in the Negro woman than in the Negro man or in the white race. This factor may explain, in part, the greater incidence of toxemia of pregnancy in the southern Negro. The reaction of the Negro to tuberculosis is well known. Any immunity the Negro may have developed to conditions in the South is quickly lost through migration northward, which brings about sudden and often extremely unfavorable environmental changes.

The relatively poor economic status of the Negro seriously influences the maternity situation. It favors poor hygienic surroundings, the cabin with no sanitary conveniences in the rural South and the congested housing in the northern cities, where the Negro becomes segregated in the oldest and poorest dwellings. Both as a result of economy and of ignorance the nutrition of the Negro is poor; this is frequently observed in the South, where the heavy salt pork diet may predispose to toxemias of pregnancy. The Negroes' poor nutritional intake favors lowered resistance to infection. Anemia of a nutritional type is a common characteristic of the pregnant Negro woman. Not only does she react poorly to hemorrhagic complications, but, as Bickerstaff[5] has shown, this anemia predisposes to a greater degree of puerperal morbidity. Rickets, a deficiency disease, with pelvic deformity and consequent dystocia is still common, though, according to Douglass,[4] decided improvement has occurred in recent years in Baltimore.

Syphilis, the outstanding social problem of the Negro, together with poor economic factors, is responsible for excessively high pregnancy wastage, which always implies a high maternal death rate. The stillbirth rate among Negroes is approximately double the white rate, and it is well known that Negro stillbirths are incompletely registered. The high Negro stillbirth rate is, of course, closely connected with the high maternal mortality rate of the race; it has been repeatedly shown that the risk of maternal death is much greater when the infant is stillborn than when it is born alive. The Negro has a high incidence of pelvic inflammatory disease; this, in turn, tends to an increase in the incidence and severity of puerperal infection.

Whether or not it is dependent on a lower moral code, crowded housing, neglect of adolescent children or a psychologic basis, there is a high rate of illegitimacy in the Negro race. Illegitimacy predisposes to the interruption of pregnancy with resulting infection, to pregnancy in the very young and to a lack of what maternity care may be available, all factors known to be associated with a high mortality rate. Frequent pregnancies and extremely large families are the rule in groups with a low economic status and decidedly affect maternal mortality; the Negro is no exception to these influences. Family planning programs which are now being carried on among southern Negroes are too recent to show a measurable effect on maternal mortality.

The largely rural distribution of the Negro in the South predisposes to home delivery, with a lack of facilities to combat emergencies and with inability to obtain prenatal care: the scarcity of physicians and economic reasons result in an inferior grade of attendant at birth—the untrained midwife.

The educational and intellectual deficiencies of the Negro favor poor obstetric results. These unfavorable factors are often discouraging to those who attempt health education programs among Negroes. The white patients fare better through years of conditioning by medical attention. The Negro's reaction to disease is primitive. He delays seeking medical aid for any condition not productive of pain. Preventive medicine is practically unknown to the Negro as he is unable, for the most part, to carry over any thought from one medical problem to another. Discussing the maternal welfare program in South Carolina, Siebels[4] says "that the Negroes are contributing nothing, and that should the clinics be closed we would revert in twelve months to our former status, if the substitution for the clinic was the voluntary selection of medical supervision by the Negroes, provided this supervision was available to them."

While the Negro has little understanding of the nature and importance of maternity hygiene and care, at the same time his medical care is insufficient and inefficient. Dowling[6] points out, in an analysis of a survey of maternal mortality, that errors in judgment and technic as well as neglect on the part of the physician were 50 per cent more frequent in the care of colored mothers.

Hospital facilities for Negroes are extremely inadequate; hospitalization of many Negro obstetric patients is of an emergency character. The increase in hospital births has been more sharply pronounced for the white than for the Negro. In 1943 more than three fourths of the white but only one third of the nonwhite births occurred in hospitals. In Baltimore, according to Douglass,[4] only 85 maternity beds are available for the Negro population of over 200,000. Comparatively few Negroes have been able to enroll in voluntary hospitalization plans, and private accommodations for the financially able Negro are scarce.

Negro physicians are too few to give adequate care to the race. In 1942 the population per physician for Negroes was about five times that for all races.[7] Present day Negro medical education is unfavorable to improvement in the ratio. The lack of hospital facilities for the obstetric training of Negro physicians adds to all the other hazards of Negro maternity patients.

The relative influence of these factors which promote a high maternal mortality rate in the Negro is difficult to appraise. The authors of a recent British report on maternal mortality found that the evidence was inadequate to permit the incrimination of such conceivably influencing factors as poverty, unemployment, overcrowding and so on. Ten years ago Tandy,[8] in discussing the mortality of the Negro mother, stated: "The more favorable situation of the white race is not suggested as an optimum expectation for the Negro but rather as an early objective to be reached through improvement in environmental conditions and through health education." Underwood[4] of Mississippi writes that through proper health education and health supervision there is no reason why the Negro maternal mortality rate should not approximate the white rate. The lack of health education and adequate medical attention may well be the crux of the unfavorable position of the Negro.

The practical application of these two principles has been effectively demonstrated in Chicago by the Chicago Maternity Center and in Alabama by the Division of Maternal Health of the State Health Department in cooperation with the medical profession.

In the Chicago Maternity Center poverty has been the only prerequisite for the home delivery service; patients have received competent care under the supervision of a trained obstetrician, adequate antepartum supervision, constant medical and nursing attendance during labor and a minimum of operative interference; and good hospitals have been cooperative and available. During the first four years of this privately supported charity, according to Tucker and Benaron,[9] the mortality rate, both obstetric and nonobstetric, for the Negroes who were attended, including those referred to hospitals, was 22. This rate was less than half the rate for white, and about one third of the rate for the nonwhite in Chicago during the same period.

In Alabama, with a large rural population, maternity clinics have been set up, supervised and financed by the state. The attending clinicians are local physicians, most of whom are white, and they work under the supervision of the state obstetric consultant. The number of clinics was 120 in 1942 and 80 in 1944. In 1943 the clinic cared for 28 per cent of all the Negro maternity cases in the state. Early registration was sought to provide ample opportunity for education, elimination of infection and thorough screening to permit early and efficient hospitalization if there were complications. Most of the Negro clinic patients were delivered at home by midwives, some were delivered at home by physicians and a few received hospital care at delivery. The three years of this service, Cunningham[10] points out, have cut the state Negro maternal mortality rate in half. The clinic rate for Negroes in 1943 was 21, the nonclinic white rate 23, the nonclinic Negro rate 52.

Obstetric care has undergone an evolution in this generation, but the Negro has not participated fully in the benefits of modern obstetrics. It is not possible to have two systems of maternal welfare, there must be one all-inclusive health program Health education and adequate maternity care for the Negro are amply provided for in the proposed national health program of the American Medical Association Conservation of human life in the process of reproduction should be shared equally by all Americans The interest and activity of the medical profession can bring this about

PRESENT STATUS OF GELATIN SPONGE FOR THE CONTROL OF HEMORRHAGE

With Experimental Data on Its Use for Wounds of the Great Vessels and the Heart

The properties of an absorbable sponge composed essentially of gelatin and designed primarily for hemostasis were first reported by Correll and Wise[1] Frantz referred to this material in a review on new methods of hemostasis which appeared shortly afterward[2] Subsequent reports by Pilcher and Meacham,[3] Correll, Prentice and Wise[4] and Light and Prentice[5] have established its usefulness, particularly from the standpoint of the problems of hemostasis encountered by the neurosurgeon Other hemostatic agents which had been previously developed were fibrin foam, which has been extensively used in neurosurgery as a result of the excellent work of Ingraham and Bailey[6] and others,[7] and oxidized or soluble cellulose (cellulosic acid) which has been the subject of extensive reports by Frantz and her co-workers[8] and by others[9]

Those who have used the fibrin foam and the gelatin sponge advocated soaking in a solution of thrombin on the premise that the sponge or foam acts primarily as a vehicle or matrix for the thrombin which was considered the primary factor in the hemostatic action of these substances Some workers have used thrombin with oxidized cellulose, although Frantz expressed the opinion that the best hemostatic effect of the cellulose is obtained in the dry state because of the slightly acid reaction of the material, i e, the cellulosic acid

Our interest in gelatin sponge was aroused from the standpoint of its possible use in the problems of hemostasis of the general surgeon

Studies on the absorption of the gelatin sponge in the liver, kidneys, spleen and abdominal wall have been reported[10] It was found that under favorable circumstances the sponge underwent absorption within about five weeks, although in the presence of a leukocytic response due to infection or damage of the tissue the sponge may become liquefied within a week or less

In studies on the hemostatic action of the gelatin sponge[11] it was found that it would control bleeding from wounds of the liver, kidneys and spleen without the addition of thrombin or the use of sutures

In view of the excellent hemostatic properties of the sponge which were demonstrated in these experiments, a wide range of tests was devised to evaluate its hemostatic properties under more critical conditions

TESTS ON ANIMALS[11a]

In a series of 12 animals a substantial portion of a lobe of the liver was resected[12] This produced rather copious bleeding The stump of liver was "blanketed" with a sheet of gelatin sponge and held with firm pressure for five to ten minutes This controlled the bleeding, and the sponge became adherent to the liver There was no secondary hemorrhage in this series, although 2 of the animals died from what appeared to be biliary peritonitis Studies of the healing of the stump of liver proved to be most interesting

Fibroplasia developed rapidly under the sponge and in addition invaded the interstices of the sponge It appears that the sponge gave protective cover to the healing process, as well as offering a lattice work for the growth of fibroblasts, thus giving reinforcement and structural support to the healing wound in the liver This is a rather fundamental point, as foreign substances generally retard rather than aid the normal process of wound repair.

[11a] The gelatin sponge used in this experimental and clinical study was provided in sheets measuring 3½ inches by 4¾ inches by ½ inch (8 9 cm by 12 1 cm by 1.3 cm) which had been sterilized by heat and packaged in sealed glass jars by the manufacturer These large size pieces of gelatin sponge could be compressed to a thickness of 1/16 inch (0 21 cm)

The gelatin sponge which was provided in smaller sizes measuring 2¼ inches by ¾ inch by ¼ inch (5 7 by 1 9 by 0 64 cm) was found to be too small to handle bleeding of any magnitude

In another series of 27 experiments[12b] in which wounds were made in the vena cava it was found that the massive hemorrhage could be controlled by a "patch" of gelatin sponge applied by pressure of the fingers for two to three minutes over the rent in the vein (figs. 1, 2, 3 and 6). When pressure was removed the patch remained adherent to the wall of the vein and controlled the bleeding completely except in 2 animals which died from uncontrolled hemorrhage.

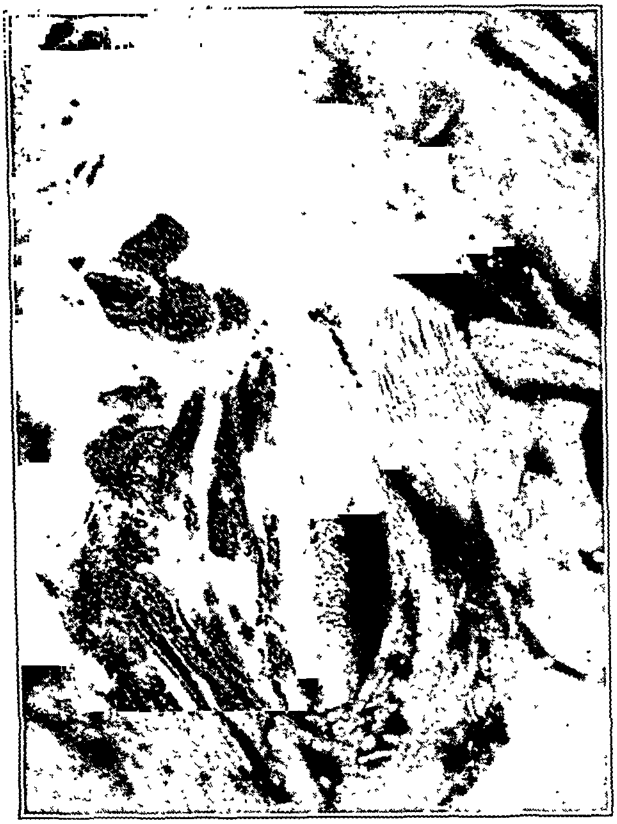

Fig. 1.—Showing hemorrhage from wound of vena cava.

In this series of animals there was secondary hemorrhage in only 1 instance in which a patch applied to the superior vena cava apparently became dislodged after the chest had been closed. The patch usually becomes sufficiently adherent within twenty to thirty minutes so that danger of dislodgment is lessened. It was generally found desirable, however, to hold the sponge in place by closing a layer of tissue such as pleura or peritoneum over the patch. After twelve hours the patch becomes rather firmly adherent to the wall of the vein. In reviewing the condition of the vein subsequently at varying periods of time it was found that the sponge firmly plugged the rent in the vein and that an endothelial layer soon covered the sponge. This endothelialization of the sponge was observed as early as four days in some instances. In a few of the specimens a small clot was observed to be adherent to the sponge, occluding the defect in the vein. Only one large mural thrombus was observed; however, in the clinical application of this phase of the work this point should be taken into consideration, and it would probably be wise to use the anticoagulants from about twelve hours to ten days. The defect in the wall of the vein was found to heal over within about two weeks by an endothelialized scar. The sponge was absorbed completely in about five weeks.

The next phase of this experimental study was to determine the hemostatic effect of gelatin sponge on arterial hemorrhage.[13] In a series of 22 dogs, incisions were made in the abdominal aorta with a scalpel after the vessel above and below had been compressed with rubber-covered clamps. In some of the experiments through and through wounds were made with the scalpel. When the clamps were released the bleeding was extensive. The clamps were reapplied, and a cuff of dry compressed gelatin sponge was wrapped about the vessel and secured in place by interrupted sutures of chromic catgut. When the clamps were again released the bleeding was completely controlled and the blood flow through the cuff restored. In five experiments there were blowouts after four to six days, in two instances due to the friability of the sponge. This technic was then modified by wrapping the cuff of sponge by a sheath of chromicized catgut and then securing the sheath by four to five interrupted chromic catgut sutures. With this technic it was possible to control hemorrhage, restore the flow of blood and prevent subsequent blowouts in 14 out of 16 animals. One blowout occurred where a plain catgut sheath was used.

A propagating thrombus is another of the hazards of any type of arterial repair, and this was observed in 1 instance.

The last phase of the experimental work has been to determine the hemostatic action of the gelatin sponge on wounds of the heart.[14] In a series of 14 dogs wounds were made with a scalpel or scissors which were often large enough to admit the finger into the ventricle. A patch of dry compressed gelatin sponge was applied over the wound and held in place by gentle pressure of the fingers synchronized with the heart beat (figs. 4, 5, 7 and 8). Bleeding was completely controlled in five

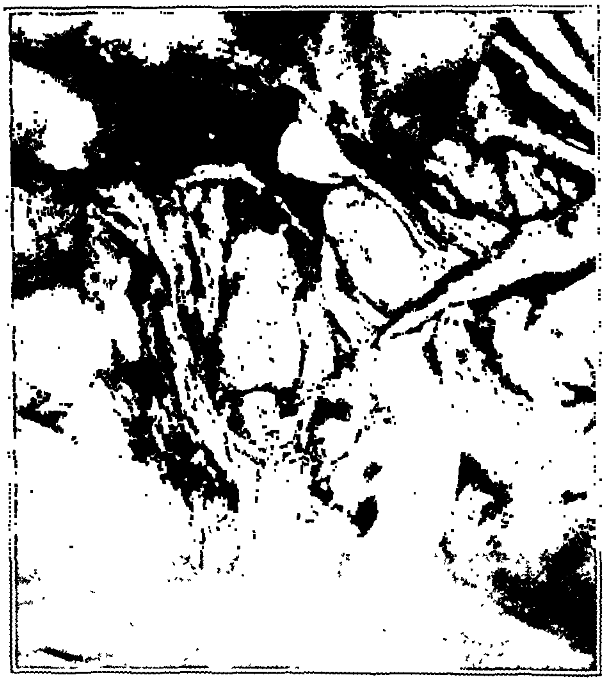

Fig. 2.—Showing control of hemorrhage by patch of gelatin sponge.

---

[13] Jenkins, H. P.; Senz, E. H.; Owen, H. W., and Jampolis, R. W.: Control of Hemorrhage from Wounds of Arteries by a Gelatin Sponge "Cuff" and Chromic Catgut Sheath, a New Experimental Method, to be published.

[14] Jenkins, H. P.; Owen, H. W.; Senz, E. H., and Jampolis, R. W.: Control of Hemorrhage from Wounds of the Heart by the Gelatin Sponge "Patch" Technique, a New Experimental Method, to be published.

to ten minutes in most instances, although it required as long as thirteen minutes in 1 experiment Within twenty to thirty minutes the patch was usually quite adherent to the heart; when attempts were made to remove the patch the sponge would not come away in one piece but would tend to fragment before it could be dislodged These animals died or were killed within two to one hundred and four days No secondary hemorrhage or blowout was observed In addition, three acute experiments were performed to demonstrate the control of the hemorrhage by this patch technic. In many of the experiments the patch was removed and a fresh patch applied several times In 6 other animals ventricular fibrillation developed as soon as the pericardium was opened or the wound made

At autopsy the patch was found to be firmly adherent to the heart and slightly adherent to the overlying pericardium. There was no evidence of blood or exudate in the pericardial cavity, and no obliteration of the pericardial sac was noted.

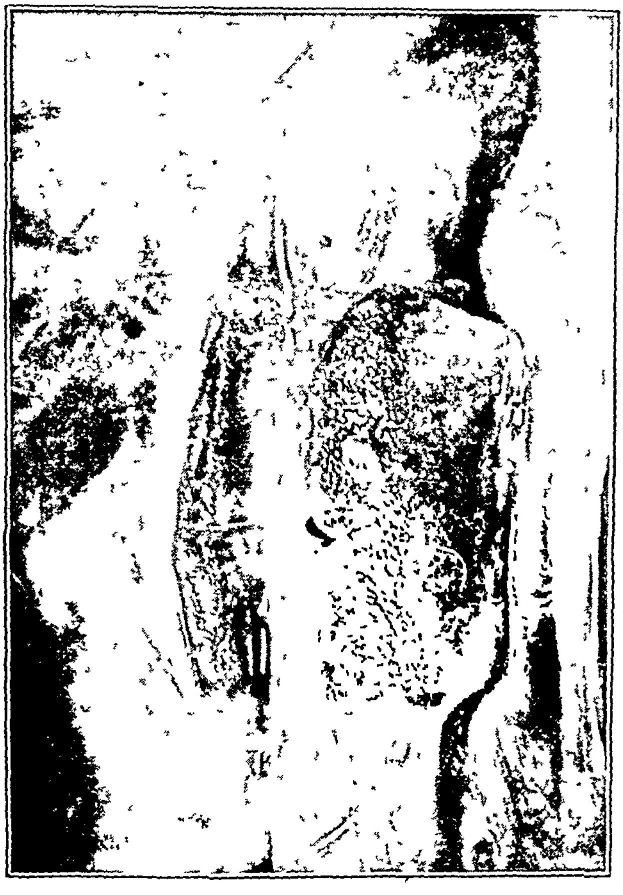

Fig 3 —Showing inferior vena cava (intrathoracic portion) thirteen days after repair of wound with patch of gelatin sponge The lungs were lightly adherent to the sponge, which was "incorporated" in the wall of the vena cava

In another series of eight experiments the bleeding from wounds of the auricles was controlled by the gelatin sponge patch technic, which required some modification from that used for controlling hemorrhage from the ventricles.[15] In most of these experiments a small portion of the auricle was excised. Two of these animals died within twenty-four hours, 1 from shock, the other from pneumothorax. The other 6 animals were killed after seven to seventy-seven days.

USE IN CLINICAL CASES AND POSSIBLE CLINICAL APPLICATIONS

In addition to these experimental tests the gelatin sponge has been used in 140 clinical cases in which there was some problem of hemostasis at operation It has been useful for control of bleeding from the under surface of the liver after cholecystectomy and from biopsy wounds of the liver After removal of the thyroid some residual bleeding in regions near the recurrent laryngeal nerves was controlled with the sponge, a method which eliminated the danger of injuring the nerves. In freeing abdominal adhesions where there may be multitudes of bleeding points, the sponge was found useful. In thoracic surgery it has been found helpful for obtaining hemostasis where thickened pleura has been excised or mediastinal tumors removed. When tissue was taken from abdominal tumors for biopsy some rather troublesome bleeding was controlled with the sponge.

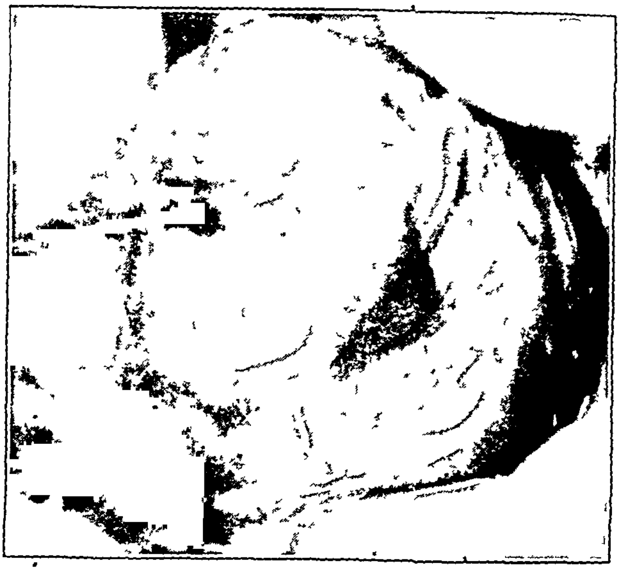

Fig 4 —Showing wound of heart (left ventricle), with scissors inserted into the wound

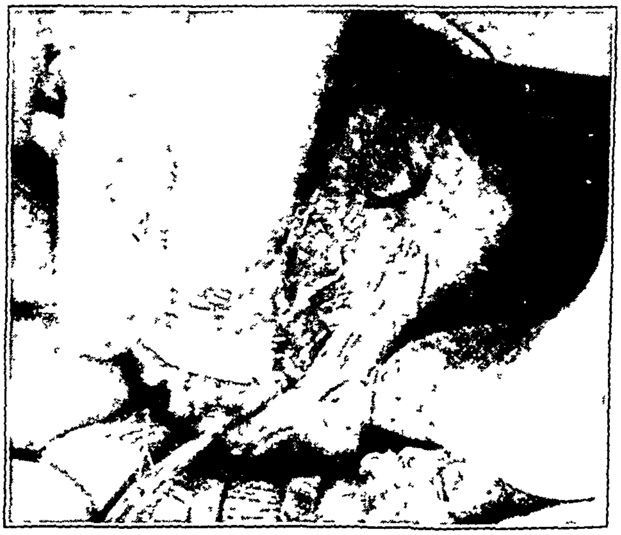

Fig 5 —Showing patch of gelatin sponge applied to wound of the heart with pressure of fingers (dry compressed sponge was used)

The gelatin sponge has also been used for control of bleeding after removal of skin grafts or granulation tissue. However, it usually becomes liquefied within one to four days under these circumstances and as a dressing for donor areas is not especially satisfactory unless the bleeding has been rather troublesome. The sponge may also be used as a pack after rectal operations, where it undergoes liquefaction within a few days and thus does not require removal. One of the more interesting uses for the gelatin sponge has been for packing the nose in cases of recurring epistaxis. It has also been found useful for packing tooth sockets after extraction, where one may sometimes encounter bleeding which is annoying.

---

[15] Jampolis, R W, and Jenkins, H P.: Control of Hemorrhage from the Cardiac Auricles by Gelatin Sponge, an Experimental Study, to be published

These clinical tests represent only the relatively minor problems of hemostasis. The real problems in hemostasis in clinical surgery remain to be tested, along the lines suggested in the experimental procedures. It should be emphasized, however, that gelatin sponge or any other hemostatic agent is not a substitute for ligature or suture in the ordinary routine technics of operative surgery. The particular field of usefulness for these new materials is where ligature or suture is not adequate or feasible.

In view of the excellent hemostatic properties of the gelatin sponge as demonstrated by the experimental tests, it should be useful as a first aid dressing for surface wounds until the patient can be cared for in an adequately equipped operating room. There are numerous instances of extensive losses of blood which might be prevented with this type of first aid dressing. It is suggested that a large pad of compressed gelatin sponge be provided with a bandage to maintain pressure and to hold the sponge in place, to meet such a situation.

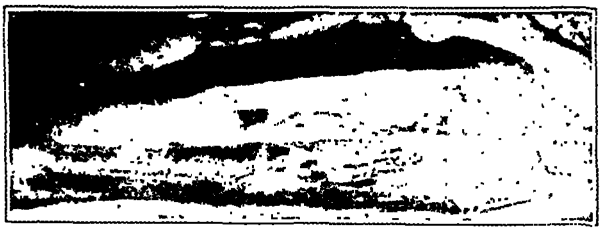

Fig. 6.—Showing vena cava forty-eight days after injury and repair with patch of gelatin sponge. Complete absorption of the patch has occurred, and the wound in the vein is healed by an endothelialized scar.

In operative surgery one of the most trying experiences which a surgeon may have is suddenly to encounter a large venous hemorrhage during the course of mobilizing an organ or tumor. There may be times when the surgeon is unable to identify the bleeding because of the lack of exposure or the magnitude of the hemorrhage, and he may be in the position of blindly applying hemostats in an attempt to control the bleeding. Under such circumstances one may damage adjacent vital structures or may be unable completely to control the hemorrhage. Gelatin sponge or the other hemostatic agents might be especially appropriate for a situation such as this. When, as is ordinarily done, gauze packs are used to control such massive venous hemorrhage it is necessary, of course, to remove the pack subsequently, and one may encounter secondary hemorrhage when this is done. When absorbable hemostatic agents are used there is no need to remove these materials subsequently, and thus the danger of secondary hemorrhage is obviated.

In the extensive dissections required in the more radical resections which are being done for abdominal malignant growths the use of the hemostatic agents may help to minimize loss of blood. Thus it may be feasible for the average well trained surgeon to perform such operations in circumstances in which there may not be unlimited amounts of whole blood available to replace the blood which may be lost in such procedures. The importance of blood transfusions when there has been extensive loss of blood during operation must not be underestimated. However, conserving blood with the aid of hemostatic agents holds much promise.

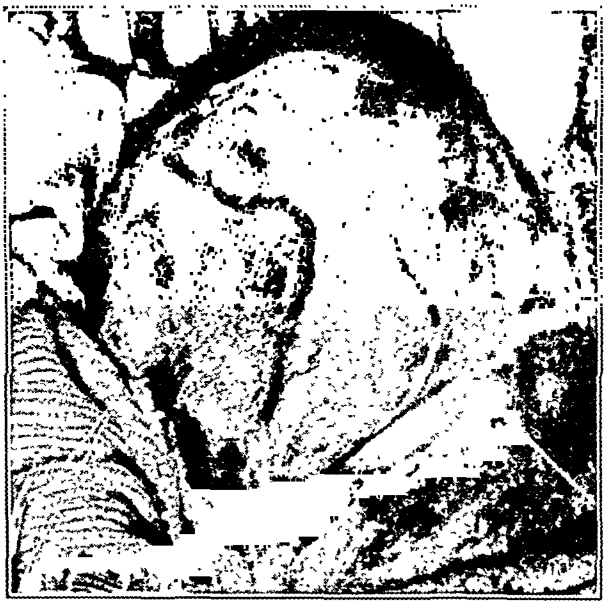

Fig. 7.—Showing patch of gelatin sponge adherent to the heart and controlling hemorrhage from the wound.

In wounds of parenchymatous organs such as the liver the gelatin sponge should be especially useful in controlling hemorrhage. In resections of tumors of the liver it may have a place as a supplement to mattress sutures. Some points in technic may have to be worked out as yet before the sponge can be used satisfactorily as the principal means of controlling hemorrhage in resections of the liver. There may be a place for a tougher and stronger spongy material which could be held in place by sutures to meet this particular problem. One of the most important points in obtaining hemostasis in the liver is an immediate firm apposition of

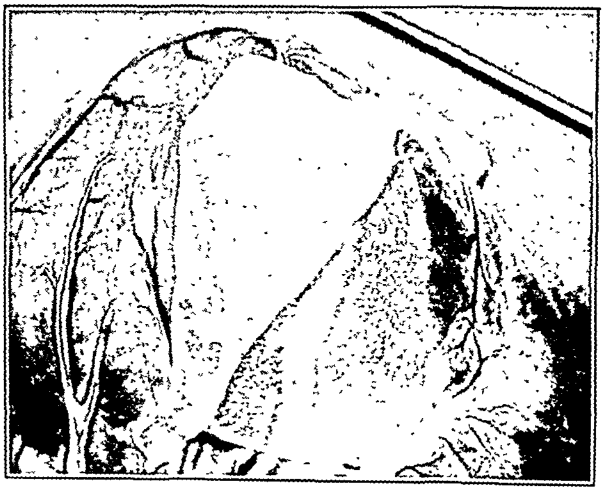

Fig. 8.—Showing heart twelve days after repair of wound of the left ventricle with patch of gelatin sponge.

the blood-soaked sponge to the bleeding surface, because the clotting of blood in the sponge before apposition is obtained negates the adhesive properties of the sponge, which are apparently due to the fibrin liberated in the clot formation. Some type of holder may have to be devised to aid in getting good apposition of the sponge to the raw bleeding surface of the liver after resection.

In operations on the bile ducts or in resections of the pancreas one may injure the portal vein. Under such circumstances it may not be feasible to perform a venisuture, and ligation, of course, would be most undesirable. In a place such as this the gelatin sponge "patch" technic may offer an alternative which would be most desirable. The neurosurgeons have used muscle, fibrin foam and gelatin sponge by the "patch" technic for controlling hemorrhages from the dural sinuses and have found this procedure indispensable to their standard technic. It is possible that the general surgeon may find this of value where there is damage to a vein which one may not choose to ligate or which may not be accessible for a satisfactory venisuture. Even if a venisuture is performed the patch of gelatin sponge may serve a useful purpose as a secondary line of defense.

In regard to wounds involving arteries where the blood flow is necessary for the viability of a limb or organ the "cuff" technic may offer some possibility for restoring vital circulation. Wherever it is feasible to perform an arterial suture it would of course be preferable, but there may be situations in which the cuff of gelatin sponge supported by a chromic catgut sheath can be utilized to maintain the arterial circulation. If arterial suture is done then the cuff and absorbable sheath may be used to supplement the suture line as a secondary line of defense against subsequent blowouts, which is of course one of the hazards of any arterial suture.

Another possible clinical application of the cuff and sheath is as a reinforcement to arterial anastomosis, which is being done in an increasing number of instances in some of the newer operations which are being developed.

In cardiac wounds the use of the sponge to stop the hemorrhage so that sutures can subsequently be placed offers one constructive point. Furthermore, a suture line can be reinforced with gelatin sponge, making it possible to tie up the sutures with less tension, thereby lessening the danger of ischemia of the muscle from tight sutures or secondary hemorrhage and subsequent tamponade from too loose a suture line. Furthermore, in small wounds, or wounds adjacent to a coronary vessel, where a suture may occlude a major branch, or wounds of the auricles, there may be a place for the gelatin sponge patch alone.

In regard to the use of gelatin sponge as a supplement or alternate to suture of traumatic wounds of the heart it would be advisable to await the evaluation of this experimental method by those who have had the widest clinical experience in this field, such as Elkin, Bigger, Blalock, Beck, Griswold, Singleton and Linder, as their work has been largely responsible for the present day method of treatment of cardiac wounds. One of the most interesting possibilities of this experimental method is that it may make intracardiac surgery more feasible, such as operations for stenosing lesions of the valves, by offering a more satisfactory means of controlling hemorrhage.

One should be extremely guarded in making clinical recommendations on the use of a new substance such as gelatin sponge or other hemostatic agents. It would be most unfortunate to have such materials misused and to have discredit brought on a valuable new agent in surgery.

There are technical points in applying the sponge which require some actual experience before one can obtain satisfactory results in controlling any severe hemorrhage. The importance of this should not be underestimated, as control of hemorrhage by the hemostatic agents may require more skill and training than is necessary to apply a hemostat adeptly or to tie a ligature. Furthermore, there are some limitations to the use of these hemostatic agents, particularly from the standpoint of the bulk of the material used. It is a fundamental principle in surgery to minimize the amount of foreign material used in a wound, and this applies to the hemostatic agents as well as to suture material or anything else. It is important, therefore, to use as small a piece and especially as thin a piece of gelatin sponge as is compatible with obtaining satisfactory hemostasis. In the presence of contamination or infection the bulk of the hemostatic agent is especially important because the gelatin sponge may become rapidly liquefied under such circumstances and may offer a culture medium which may influence the development of infection.

MODE OF ACTION OF THE GELATIN SPONGE

In regard to the mode of action of the gelatin sponge in obtaining hemostasis it would appear that the most substantial factor in the control of bleeding in this study has been the gelatin sponge itself, as nearly all the experimental and clinical observations described were made without the addition of thrombin to the sponge. Control studies using sponge rubber, Du Pont cellulose sponge and sea sponge demonstrated a hemostatic action on wounds of the vena cava and the heart which was similar to that of gelatin sponge, although it was not so satisfactory and did not adhere so firmly to the wound. The hemostatic action of thrombin is of course incontestible. The extent to which thrombin may enhance the hemostatic effect of substances such as gelatin sponge was not at all clearcut in our experience.

The clotting effect of the sponge may be due to the liberation of thromboplastin when the platelets in the blood entering the sponge become damaged by contact with the walls of the myriads of interstices, which present a rather large surface area. The thromboplastin thus liberated along with the prothrombin and calcium in the blood may then produce enough thrombin to initiate the clotting mechanism. Thus one may be dealing with a physiologic formation of thrombin in the sponge which is adequate to produce a clot by its action on the fibrinogen of the blood without the addition of prepared thrombin.

In conditions in which there is a deficiency of prothrombin or platelets it would obviously be desirable to have prepared thrombin in the sponge to obtain satisfactory hemostasis. Until such time as more data are available on the extent to which thrombin may appreciably enhance the hemostatic effect of gelatin sponge in the absence of deficiency in the normal clotting mechanism it is recommended that thrombin be used with gelatin sponge in clinical cases.

The important and fundamental aspect of this work is the spongy physical properties of the gelatin sponge, which hastens the formation of a clot when the blood enters its interstices and then gives structural support to the clot. Furthermore, this "reinforced" clot becomes adherent to the wound because of liberation of fibrin during the clotting process. In addition, there is the role of the sponge in giving protection and support to the process of wound repair by permitting fibroplasia to develop under the cover of the adherent sponge as well as into the interstices of the sponge. And finally the sponge undergoes absorption after it has served its purpose of aiding two of the most important protective mechanisms of the body, the clotting of blood and the reparative process.

It is entirely possible that other spongy substances may be developed which would have some advantage from the standpoint of stronger and tougher physical properties which would be helpful in some of the problems of hemostasis, such as for work on the liver, the arteries or the heart, and would still retain the absorptive and protective qualities found in gelatin sponge.

In view of the possibilities of the development of a number of hemostatic agents there should obviously be some attempt made to obtain standardization of the properties of absorbability and the controls of sterility which would protect the surgeon and the patient. It would be appropriate for the Council on Pharmacy and Chemistry of the American Medical Association to make some recommendations on this problem. From our studies there appears to be a place for three grades of material from the standpoint of properties of absorbability: (*a*) a type which is rapidly absorbed (one to three weeks); (*b*) a type which is absorbed in a medium length of time, such as the present type of gelatin sponge (three to six weeks), and (*c*) a type which is absorbed slowly, where there may be a greater degree of resistance to the action of leukocytes (six weeks to six months).

SUMMARY

Experimental data on the use of gelatin sponge for control of hemorrhage from the liver and from the wounds of the great vessels and the heart have been presented. Clinical observations have been made on 140 cases in which the gelatin sponge has been used for hemostasis as a supplement to ligature or suture.

CONCLUSIONS

The absorbable hemostatic agents are a contribution to the practice of medicine and especially to surgery. Gelatin sponge has been studied experimentally and clinically and found to have desirable properties from the standpoint of absorption and hemostatic action, as well as some limitations. The gelatin sponge is a valuable addition to the field of the absorbable hemostatic agents.

These materials will undoubtedly contribute to a greater degree of safety by conserving blood loss, not only in the first aid treatment of surface wounds, where hemorrhage may be the principal immediate problem, but also in operative procedures generally.

There is no place for controversy with respect to use of the hemostatic agents in place of ligature or suture when these would ordinarily suffice. The principal field of usefulness of the hemostatic agents is where ligature or suture is not adequate, feasible or desirable, or as a supplement to suture.

With the aid of hemostatic materials now available as well as with those which may yet be developed, there may be a widening of the scope of operative surgery, especially in the field of vascular and cardiac surgery and in the operative attack on malignant tumors.

ABSTRACT OF DISCUSSION

DR. VIRGINIA KNEELAND FRANTZ, New York: It has been a matter of great interest to observe the origin and development of a number of absorbable packings since the appearance of the pioneer in the field, fibrin foam, at Harvard University There are now three such substances which have been the subject of extensive clinical as well as animal experimentation They are fibrin foam, oxidized cellulose and gelatin sponge. All these materials are nonirritating and absorb completely in the tissues in varying lengths of time. With more widespread clinical trial we await the verdict of surgeons and of general practitioners, who still see a good deal of bleeding, as to the relative merits of each of these agents. The particular technics which control hemorrhage from the heart and great vessels which Dr. Jenkins presented are dramatic and somewhat terrifying He has been wisely cautious in extending the application to exactly similar technics in human surgery. There is no doubt, however, that the hemostatic absorbable pack is here to stay for the control of bleeding—often major arterial bleeding—which cannot be handled by other means, and for more radical surgical procedures than were formerly possible, and, as Dr. Jenkins pointed out, for the first aid, first treatment of the severe hemorrhage before definitive surgery can be achieved. Clearly, the experimental studies of Dr. Jenkins are designed to give the surgeon courage in the face of what could be disaster.

DR. HILGER PERRY JENKINS, Chicago: The principal thing we have to present is the fact that these new hemostatic agents, fibrin foam, oxidized cellulose and gelatin sponge, will be helpful in saving lives by conserving loss of blood. We do not know all the clinical applications as yet of the experimental studies which have been conducted. It is only by the wider use of these hemostatic agents that we may ultimately have the answer to some of these problems. Extreme care should be used in exploring the clinical value of these new materials, and it should be emphasized again that they are not designed as a substitute for ligation and suture when this would ordinarily suffice.

Heterogeneous Mesenchymal Cells.—The reticuloendothelial system, as originally conceived by Aschoff, unites a multitude of heterogeneous mesenchymal cells widely dispersed throughout the animal body according to one functional similarity—the ability to store colloidal dyes in granular form. The individual members of the system, such as the reticular and endothelial cells of lymph nodes, spleen and bone marrow, the stellate cells of the liver and the mononuclear, ameboid cells of the loose connective tissue (clasmatocytes), had been identified by histologists many years before but their biologic relationship had not been realized on morphologic grounds. Yet certain of their functional abilities such as phagocytosis of foreign material and the faculty of fiber formation had been fully recognized before and their potentialities of progressive differentiation had been conjectured at by investigations of histologists, embryologists and pathologists. While in Aschoff's original conception the storage ability of the reticuloendothelial system was singled out, subsequent investigations disclosed additional functional aspects. The fundamental feature of the system is its reactivity to a variety of stimuli which provoke cell proliferation and differentiation in contrast to other cells of mesenchymal origin which represent final developmental stages. The cells of the reticuloendothelial system of the adult organism have retained part of their embryonal potencies which can be reawakened by adequate stimulation. The main lines of differentiation are the histiocytic-macrophagic, the hematic, endothelial and fibroblastic —Klemperer, Paul: The Reticulo-Endothelial System, *Marquette Medical Review*, August 1946.

SYMPATHECTOMY FOR REFLEX SYMPATHETIC DYSTROPHY

Report of Twenty-Nine Cases

JAMES A. EVANS, M.D.
Boston

Reflex sympathetic dystrophy or causalgia is a painful syndrome usually occurring after trauma to a limb, characterized by its own peculiar type of burning, diffuse pain, trigger points and manifestations of sympathetic stimulation such as, subjectively, a cold or hot limb and, objectively, rubor, pallor, or both, and swelling. There is often atrophy of the bone, characteristically mottled owing to spasm of the nutrient arteries, and sometimes atrophy of the skin and muscle. There may even be immobility of a joint, scleroderma and Dupuytren's contracture.

An attractive theory of the mechanism of this pain is adopted from De Nó[1] by Livingston[2] in his monograph on "Pain Mechanisms." I have slightly modified this conception in figure 1. A prolonged bombardment of pain impulses sets up a vicious circle of reflexes spreading through a pool of many neuron connections upward, downward and even across the spinal cord, and perhaps reaching as high as the thalamus itself. Because of the summation principle of nervous impulses and of the "facilitation" of conductivity within the spinal cord as described by Porter and Taylor,[3] there is kept alive within such a pool a constant circling of activity across the synapses involved. Some of these synapses include the sympathetic motor neuron cells in the lateral horn, controlling vasomotor tone and the sweat glands. Spasm in the arteriolar and venule end of the capillary loops raises filtration pressure, and edema and swelling result. Cyanosis and anoxemia increase capillary permeability and filtration, further augmenting edema. Other synapses involved may be the anterior motor horn cells, giving rise to cramps and spasms of the skeletal muscles. Augmented stimuli to pain also flow out of the pool, traveling up the thalamic tract. Depending on the extent of the pool, the phenomena of pain and sympathetic disturbances are observed a long distance from the injured area of the body and occasionally even spread to the contralateral side.

De Takats[4] has recently reviewed 54 cases of causalgic states, in which he recognizes three sensory levels, peripheral, spinal and cortical, based on lesions of the first, second and third neurons, and advocates direct treatment to the affected neuron. With few exceptions my colleagues and I have employed therapeutic attack on the second neuron, namely the sympathetic pathway, either by sympathetic nerve block with metycaine hydrochloride or by sympathectomy. It is our conviction that the majority of these patients can be relieved by these two methods of attack. Treatment of the trigger points alone is not satisfactory in our experience in dealing with severe causalgic states and has been used chiefly as an adjunct to sympathetic nerve block with metycaine hydrochloride and sympathectomy.

In a recent review of 57 patients with reflex sympathetic dystrophy at the Lahey Clinic, 12 were treated by sympathetic nerve block alone, in 11 of whom there was satisfactory to complete relief. Twenty-nine others submitted to sympathectomy after sympathetic nerve block with procaine hydrochloride demonstrated only temporary relief in all but 2. It is important to note that these 2 patients who received no relief of pain from sympathetic nerve block were not relieved of their pain after sympathectomy, although sweating, rubor, pallor and swelling disappeared.

We have resorted to sympathectomy in many of these patients after trying one block, rather than waiting for results from a series of blocks and injections into trigger points because of the severity of most of these patients' syndromes, their prolonged suffering, the distance from which they came to us, for quicker rehabilitation to normal economic status and because in the hands of Dr. Poppen,[5] of our neurosurgical staff, sympathectomy is an operation attended by no risk of mortality and only two weeks' hospitalization.

The results of sympathectomy with regard to pain are given in table 1. Ten patients had complete relief of pain for follow-up periods of one month to two years. One patient who was followed up for less than one month had complete relief. Eleven patients had 50 to 90 per cent relief for periods ranging from one month to two and one-fourth years. Seven patients had no, or but little, relief of pain.

A review of the 7 failures (table 2) seems of more value in the study of this syndrome than a detailed report of the success of what is now accepted as a standard treatment. Two glaring pitfalls appear: (1) 2 patients who were not relieved of pain on block were not helped whatsoever by sympathectomy, at least with regard to their pain; (2) 2 patients not included in this series did not have sympathectomy performed because false blocks temporarily relieved their pain after true blocks had produced complete, dramatic relief.

From the Department of Internal Medicine, The Lahey Clinic.

Read before the Section on Nervous and Mental Diseases at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

[5] Five of these patients were operated on by Dr. Ralph Adams of the general surgical staff.

The psychosomatic background of patients with reflex sympathetic dystrophy is like that of patients with Raynaud's disease and hysteria, and "litigation neurosis" must be carefully appraised in these cases with the help of the psychiatrist.

One of the 2 patients who did not receive relief from either block or sympathectomy had sustained a fracture of the right ankle three years previously. Her pain was severe, of the causalgia type; trigger points, rubor and swelling were present. For three months following sympathectomy she was considerably better and was able to abandon crutches. At a follow-up examination nine months after operation, however, her pain was as severe as ever, although a good effect of the sympathectomy was evident and swelling was no longer present. Electric skin resistance test showed regeneration of sympathetic nerves, which must have recurred within three months. Parenthetically, a study by Dr. Richter[6] at the Lahey Clinic of such sympathetic regeneration after sympathectomy for hypertension has been most illuminating and constitutes a challenge to the present technic of sympathectomy. On this patient it was necessary to perform neurectomy of the distal peroneal and sural nerves, which finally gave her relief of pain. We felt that this procedure was preferable to attack on the spinal neuron (by cordotomy).

The second patient who received no relief of causalgic pain one year after either block or sympathectomy had suffered a laceration of the hand and had two repair operations one year previously. She had severe causalgic pain. Trigger points, pallor, sweating and atrophy of muscle and bone were present. It was decided that in a patient with her psychosomatic background a third resection of the scar on the wrist with necessary pedicle graft would be inadvisable. Previous local operations had only aggravated her pain, a fact emphasized by Livingston. Since her case is still in litigation, we have advised immediate settlement and have seriously proposed a visit to a well known religious shrine before such radical measures as attack on the spinal neuron (thalamic tract resection) or at the cerebral level (lobotomy or cortical resection) are considered.

The third patient who had no relief following sympathectomy had his operation done elsewhere, and a diagnostic block, advised by us, was not carried out first.

A fourth patient we feel needs scalenectomy for further relief.

The fifth patient who received absolutely no relief from sympathectomy suffered a peculiar pain in the left arm, axilla and left side of the chest, often provoked by effort but more often coming on while he was lying down. Successful treatment of subacromial bursitis on the left side gave him no permanent relief. Three paravertebral sympathetic nerve blocks with metycaine hydrochloride and two trigger blocks gave him complete but temporary relief. Upper thoracic sympathectomy on the left side afforded him relief for only two or three weeks, and two months later he reported full return of angina of effort.

For 1 of 2 patients who received only about 25 per cent relief following sympathectomy an additional exploration of the radial nerve is advised, and the other needs continued physical therapy for pronated feet.

Two unusual cases of reflex sympathetic dystrophy in which there was successful relief of symptoms by sympathectomy are reported.

REPORT OF CASES

Case 1.—A man, aged 64 was admitted to the New England Deaconess Hospital Aug. 18, 1945, with pain and swelling of the left hand and forearm of five months' duration. A year before admittance itching and discomfort of his nose had developed, with several small ulcers inside the nose. When these failed to heal, a Wassermann test was made, results of which were reported to be "questionably positive." He was then given an injection of a bismuth compound into the left cubital vein. As the injection was being given, the patient jumped and some of the bismuth compound was injected outside the vein. Shortly thereafter a lump about 4 by 8 cm. formed on the arm. Two weeks later a spot on the left thumb became painful, tender, red to purple and hot. This spread to involve the entire hand and wrist. At times the fingers became pale and cold, and the nail beds became white. A rash was present for three weeks on the dorsum of the left hand.

Examination showed the wrist and fingers of the left hand to be slightly swollen. The skin was smooth, pink and atrophic. There were loss of wrinkles and pitted nails. Ulnar deviation of the wrist was present. The metatarsal phalangeal joints were slightly flexed. The interphalangeal joints of the four fingers were immovable. There was atrophy of the left shoulder girdle. Pigmentation of the skin, with scaling, was noted over the left pectoral and left supraclavicular regions. There was partial immobility of the left shoulder, especially with respect to external rotation. A diagnosis was made of reflex sympathetic dystrophy, with secondary atrophy of the bone, muscles and joints and immobility of the finger joints.

Diagnostic block not done at first	1	
Scalenectomy needed	1	
Angina of effort returned	1	
25 per cent relief only		2
Exploration of radial nerve advised	1	
Continued physical therapy for pronated feet advised	1	

Sympathetic block of the cervical chain on the left side was carried out on August 22, with the following results: 1. Shortly after the block, the skin of the left hand became redder. One hour later, when the hand was being held in the dependent position, it became cyanotic. 2. There was definitely decreased pain in the fingers, hand and wrist, with abolition of pain at the trigger point at the base of the left thumb. 3. There was increased passive mobility of all the finger joints and the wrist. 4. Cutaneous temperature readings taken on the dorsum of the hand, thumb and forefinger showed a definite increase, a total rise in one hour of 6.3 F. Because of long disuse of the extremity, the patient had a "frozen left shoulder." The orthopedist manipulated the shoulder under local anesthesia, breaking down fibrous adhesions. Four days later cervical sympathectomy on the left side was done by the anterior approach. On the fourth postoperative day bronchial pneumonia developed, which subsided on sulfathiazole therapy. *On discharge the patient was given instructions to* use melted paraffin to the hand and given directions as to special exercises.

---

[6] Richter, C. P.: Personal communication to the author.

Nine months after discharge some scleroderma was still present over the second and third fingers and palmar contraction persisted. The left shoulder had full motion. The fingers were more mobile, all pain had disappeared, and there was no more atrophy of the muscles of the chest or shoulder and the pigmentation and scaling of the skin over the left pectoral region were entirely gone. Recalcification had occurred in the humerus and bones of the hand and wrist (fig. 2).

Case 2.—A woman aged 33 entered the New England Baptist Hospital on May 10, 1945, complaining of excruciating pain in the right arm, shoulder and breast, of five years' duration. Six weeks before the onset of this pain she had fallen on the right elbow, and the roentgenologist reported that she had sustained a "chip fracture of the olecranon process." The trouble began as a painful swelling of the right forearm, diagnosed as neuritis. The tonsils and appendix were removed as possible foci of infection, without relief. Next, the arm itself was explored and a biopsy specimen was taken. The pathologic report was periarteritis nodosa

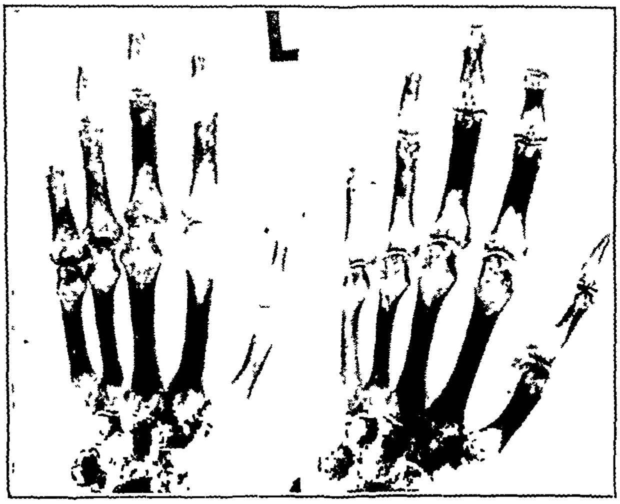

Fig. 2 (case 1).—Roentgenograms of hands; left, preoperative; right, nine months after sympathectomy, showing recalcification of the bones of the hands.

In 1942 a nerve block proved ineffective. In 1943 relief was obtained after a scalenectomy, but there was a return of symptoms in 1944, attended by severe epistaxis.

Examination revealed a Raynaud-like syndrome, with trigger points over the scar on the right arm, the olecranon process, the posterior and medial surface of the upper part of the forearm, the back of the right shoulder and the right posterior aspect of the neck about the level of the second and third cervical vertebrae. Another trigger point was present in the lateral second interspace on the right. Exposure to cold produced whiteness of the hand and forearm, followed by blueness. Extreme cold caused complete numbness of the right little finger and proximal interphalangeal joint, the latter becoming black in color. The patient stated that when the pain started the right shoulder, breast and arm felt cold, became pale and then swelled, after which the hand became white and then blue. This phenomenon was observed during the examination. There was a palpable difference in temperature of the upper part of the arms. Sweating of the right axilla and hand was noted. There was atrophy of the tips of the fingers in both hands, more marked on the right, with tapering especially of the tip of the right little finger. The right radial pulse during a paroxysm of pain was barely perceptible. It was thought that her episodes of pain in the left arm might be the contralateral effect sometimes seen in causalgia.

On May 14, 1945, the patient was put out on a porch, where the air was cooler. When she was turned on her left side and the right arm and shoulder were exposed, the arm became painful and was mottled and cyanotic from the shoulder down to and including the hand. A paravertebral block with metycaine hydrochloride was done of the seventh cervical and first and second thoracic segments. Almost immediately after the metycaine hydrochloride was injected the patient said that her arm felt warmer and the pain was diminished. Fifteen minutes after the injection was completed, the arm was pink and warm. She said there was no pain whatsoever by this time. The trigger areas had disappeared.

With this evidence thoracic sympathectomy on the right side was performed, including the thoracic second and third sympathetic ganglions. After sympathectomy, the pain on the right disappeared and the flushing and sweating phenomena abated.

About a week after sympathectomy on the right side the patient began to complain bitterly of similar symptoms on the left side. A block of the upper thoracic sympathetic nerves caused temporary disappearance of this pain. A thoracic sympathectomy was therefore done on the left side, including the second and third thoracic segments. The patient was discharged on the twenty-fifth hospital day asymptomatic.

Four months after discharge from the hospital, however, the pain and sweating returned in an area lower on her chest than the previous symptoms. Sympathectomy was now extended in two stages down through the second lumbar segment. When the patient was discharged from the hospital two weeks later all causalgic pain had disappeared.

SUMMARY AND CONCLUSIONS

A theory of the mechanism of pain in reflex sympathetic dystrophy is presented.

Sympathectomy was performed on 29 of 57 consecutive patients with reflex sympathetic dystrophy seen in the last five years.

Eleven of the 57 patients received adequate relief by one or more sympathetic nerve blocks with procaine hydrochloride, sometimes reenforced by trigger block.

Temporary relief by sympathetic nerve block with procaine hydrochloride indicates the need for sympathectomy.

Failure to obtain relief by sympathetic nerve block with procaine hydrochloride makes relief by sympathectomy unlikely, even if other symptoms of sympathetic dystrophy besides pain are objectively present.

Twenty-two of 29 patients (76 per cent) on whom sympathectomy was performed for reflex sympathetic dystrophy obtained satisfactory to complete relief of pain. Two more patients received only slight relief of pain and need further surgical or physical therapeutic measures for complete relief, measures which we have found are more likely to succeed when the sympathetic pathway is cut.

Sympathectomy should be done, therefore, before necessary local surgical procedures or painful physical therapeutic measures are attempted.

Five patients (17 per cent) received no relief whatsoever. Two of these patients had received no previous relief from sympathetic nerve block with procaine hydrochloride and this fact would seem to preclude the success of sympathectomy. Of the remaining 3 patients, 1 did not have a previous diagnostic block, 1 needs scalenectomy and the last has complicating angina of effort.

The possibility of rapid regeneration of sympathetic nerves militates against permanent good results of sympathectomy in some patients.

ABSTRACT OF DISCUSSION

Dr. Geza de Takats, Chicago: One can hardly overemphasize the importance of Dr. Evans's contribution. The syndrome of reflex dystrophy or, what is a broader term, the causalgic state, is far more frequent than is ordinarily supposed. It not only appears after comparatively mild, blunt trauma affecting the terminal parts of the extremities, but it plays a role in the symptomatology of such disjointed conditions as rheumatoid arthritis, diabetic neuropathy, adhesion pains after laparotomies and many other lesions in which there exists a chronic continuous stimulation of sensory pathways which produces chronic sensory, vasomotor and motor phenomena. I agree with Dr. Evans that the early effective block of the sympathetic pathways is the most satisfactory method of treatment. His careful analysis of failures reemphasizes the importance of never advocating sympathectomy unless relief from pain has been obtained by procaine block of the sympathetics and secondly that incomplete sympathectomies may result in failure or recurrence. It is now sufficiently clear, particularly from army experience, that sympathectomy for causalgia of the lower extremities must be so extensive that it may necessitate the resection of the eleventh and twelfth thoracic ganglions along with the first and second lumbar ganglions. No such difficulty seems to be encountered in the upper extremities, where resection of the second and third ganglions with root section of the second and third intercostal nerves is sufficient. That long-lasting causalgias have difficulty because of stiff joints, short tendons and atrophic muscles simply reemphasizes the importance of early recognition and treatment of such states. Compensation neurosis and hysteria are the two great hurdles in this field. One must insist on early settlement, and it is doubtful whether any such patient should be treated before settlement is reached. The value of sham injections is also obvious; the dramatic long-lasting relief from procaine injections must be analyzed with the help of injecting isotonic solution of sodium chloride through procaine wheals; recently 2 patients received relief from this procedure, thereby dissuading me from doing a sympathectomy. A word should be said about the mechanism of relief following sympathectomy. If this were a reflex sympathetic dystrophy, as I suggested in 1937, sympathectomy would cut the efferent arc of the reflex; but many observations which have accumulated since then make me suspect that this is a true antidromic, sensory nerve stimulation which is certainly unwisely treated by local excision and which responds to sympathectomy because section of the sympathetic efferents diminishes the number of impulses reaching the injured, irritable noninsulated sensory neuron. The sympathectomized extremity, even in a noncausalgic limb, has a raised threshold for pain, a fact which explains many a puzzle of the so-called extrasensory auxiliary pathways for pain.

Captain W. K. Livingston (MC), U.S.N.R.: Dr. Evans is to be congratulated. Out of 29 cases a ganglionectomy failed to afford a substantial or complete relief in only 7 cases. I would consider these results exceptionally good. Dr. Evans is correct in stating that when a preliminary procaine block of the sympathetics fails to afford temporary relief it is reasonable to assume that a ganglionectomy will probably fail. I would add the fact that even when the procaine block affords temporary relief the ganglionectomy may fail to confer a satisfactory result. In my opinion there are three reasons why this should be so: 1. The phase of active vasodilatation which follows immediately after a block or a ganglionectomy does not persist for long, and although relief may be obtained during this primary phase, the pain may recur when the vessels regain some tone. 2. Sympathetic nerves have a remarkable ability to regenerate. I have had the disappointing experience of seeing pain return a few weeks after ganglionectomy and have been able to demonstrate that within two or three months sympathetic fibers have successfully bridged a considerable anatomic gap. 3. These so-called sympathetic dystrophies begin as a result of irritation at some focal or "trigger point." A sympathetic ganglionectomy does not remove this source of irritation, and not infrequently the pain and many of the associated dystrophic phenomena will recur even in the absence of the sympathetic component. In my opinion the most significant feature of this paper is the fact that 11 of 12 patients treated with procaine block alone were completely cured of their pain. These 11 patients represent almost 20 per cent of this whole series. The fact that procaine block gives a satisfactory result without the need to resort to a surgical excision indicates to me that the syndrome represents a disturbed physiology which the injection acts in some mysterious manner to correct. I am always in favor of trying repeated procaine block of the sympathetics before resorting to the use of alcohol or a surgical excision of the ganglions for three reasons: 1. I hesitate to excise sympathetic ganglions which in their normal state must serve useful functions, some of which functions we may not yet understand. 2. When a surgeon excises the sympathetic chain he has removed the point of attack at which the syndrome is most vulnerable. 3. Since I believe that this is a disturbance of physiology, I would prefer to treat it with physiologic methods rather than surgical excisions. This paper emphasizes two points which are of great importance to the clinician who undertakes to treat painful dystrophies. One of these is that the sympathetic nerves play an important part in sustaining the dystrophy and represent the most logical point for surgical attack. The second point is equally obvious in this paper, that is, a sympathetic ganglionectomy is not a cure-all for painful dystrophies.

Dr. James A. Evans, Boston: I thank Dr. de Takats and Dr. Livingston for so ably discussing this difficult problem. I do not want to leave the impression that sympathectomy is a cure-all for this syndrome. It is a very difficult kind of case to handle in many instances. One must not lose sight of the psychosomatic feature of these cases, and fake blocks are often necessary to bring this out. Litigation neurosis enters into this again and again, as has been pointed out. I also want to state that a series of blocks will cure many of these patients without having to resort to the more radical sympathectomy.

THE MALARIA PROBLEM TODAY

Influence of Wartime Experience and Research

CAPTAIN JAMES J. SAPERO
Medical Corps, United States Navy

In dealing with present day problems of malaria, attention in this paper will be centered on potential benefits forthcoming as a result of wartime experience and wartime research. From this experience and research, important advances in the field of malariology have followed. In particular, they have contributed to improved methods in the treatment of malaria and to new approaches in regard to prevention.

CLINICAL MALARIA

Army and Navy statistics[1] for World War II reveal a total of 572,950 reported admissions for malaria. Actually, it is probable that, had complete reporting been possible, the total would have more nearly approximated a million admissions. Whatever the exact figure, clinical experience on an unprecedented scale was gained, and as a result many interesting and exceedingly important developments took place in the field of clinical malaria.

Substitution of Quinacrine Hydrochloride for Quinine.—A development of foremost importance is that during World War II quinacrine hydrochloride displaced quinine from its agelong position of preeminence.

Malaria and Epidemic Disease Control Officer, South Pacific Area (1942-1944) and Pacific Ocean Areas (1944-1945).

Read in the General Scientific Meetings at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 2, 1946.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the United States Navy. The opinions and views set forth in this article are those of the writer and are not to be construed as reflecting the policies of the Navy Department.

[1] Sapero, J. J.: Tropical Diseases in World War II Returnees, to be published.

As a result, never again will it be necessary to face the serious problem of an irreplaceable shortage of quinine such as that which occurred early in the war when most of the cinchona plantations fell into the hands of the enemy.

Although the drug had been known for some years, even before the outbreak of the war, it had never come into general use. Instead, almost full reliance had been placed on quinine. The relatively small number of physicians who had had experience with quinacrine hydrochloride were not certain concerning either its therapeutic capabilities or its toxic potentialities.

As quinine became more and more scarce during the war, physicians found themselves forced to use quinacrine hydrochloride. It became apparent soon that the clinical response to this drug was equivalent to that of quinine. In regard to the toxicity of quinacrine hydrochloride, overseas experience demonstrated, contrary to previously expressed opinions, that the drug had an exceptionally low toxic factor. It is true that initial gastrointestinal intolerance occurred, but this shortcoming was largely corrected by adjusting the initial dosage. The claims that hepatitis, psychoses and other severe toxic manifestations would occur were not substantiated. It seems probable, in fact, that the exceedingly infrequent serious toxic manifestations which did take place actually did so less commonly than would have been the case had quinine been used on a like scale.

Incurability of Pacific Malaria Due to Plasmodium Vivax.—With the establishment of quinacrine hydrochloride as an efficient and safe antimalarial, the next problem which arose was the failure of either quinine or the other drug to cure the South Pacific strain of malaria due to Plasmodium vivax. After treatment of the primary attack, this strain of malaria almost inevitably relapsed, did so promptly and continued to relapse with discouraging persistency, irrespective of treatment. This was unlike clinical experience with malaria due to P. vivax in the United States. It was characteristic of the primary attack of the American strain to respond promptly to treatment. There would then follow a latent period of some seven to eleven months before relapses were to be expected. Further, the average duration of infection was shorter. American infections caused by P. vivax terminated usually within a period of eighteen months; South Pacific infections, in contrast, continued frequently on into the third year.

The Search for a Curative Drug.—The exceedingly discouraging experience in the attempt to cure South Pacific malaria due to P. vivax led to an unparalleled program of research, both in the United States and elsewhere, in an attempt to synthesize a drug capable of curative effect. As a result, a large series of chemicals were explored and subjected to clinical tests. One of these, originally referred to as SN-7618 and now officially known as chloroquine,[2] has reached the stage of practical clinical application. This drug, against well standardized strains of Plasmodium falciparum and P. vivax, has shown an activity approximately three times that of quinacrine hydrochloride. To date it has presented little evidence of toxicity. It does not cause the gastrointestinal intolerance so frequently encountered in using quinacrine, nor does it stain the skin. Furthermore, it rapidly controls clinical symptoms in both the P. vivax and the P. falciparum types of malaria and is curative in the latter. In benign tertian infections it is not curative but tends to prolong the intervals between relapses beyond that observed with either quinacrine hydrochloride or quinine.

Although it appears that chloroquine may be superior to both quinine and quinacrine as an antimalarial, its failure to cure malaria caused by P. vivax has necessitated further investigation in the hope that a curative drug may be found. In the course of such investigations, it has been found that pamaquine, as had been previously claimed, is capable of curing malaria due to P. vivax. Unfortunately, the curative dosage is close to the limit of tolerance and too toxic to serve as an answer to the present need for a curative drug.

Pentaquine (SN-13276), which is closely related to pamaquine, has been recently explored and found to be approximately equal in activity and only half as toxic. Although it represents a promising lead, further search is being made, as there is a need for a drug of even less toxicity. Much publicity recently has been given to Paludrine, a recent product of British investigation. This antimalarial has a chemical formula (N_1-p-chlorophenyl-N_5-isopropyl biguanide) which differs from that of any drug so far tested. From present indications, however, it will not cure benign tertian malaria and thus from a practical point of view does not seem to be superior to chloroquine.

New Concepts of the Parasitic Cycle in the Human Host.—The confusion which followed when South Pacific infections caused by P. vivax failed to respond to therapy in a manner similar to that of the American strain can readily be realized. It is now known that this confusion was largely unnecessary. It was a result of improper concepts which for years have been passed along in the general teaching in regard to malaria. The cycle of the parasite in the human host has been generally taught to be a simple parasitic invasion of red cells, taking place shortly after mosquito inoculation of sporozoites. Thereafter, almost total emphasis has been placed on the periodic, cyclic development of the parasite in the red blood cells. The concept, in regard to treatment, has further postulated that if drugs are given in adequate amounts and for a sufficient length of time, the parasites in the red cells will be destroyed and the infection cured.

With such a version, the tendency is to ascribe therapeutic failure or success directly to the precise method of treatment with a drug. Thus, in the case of the South Pacific strain, relapses and persistency of infections were thought to be essentially an expression of the failure to use adequate dosage or failure to prolong therapy sufficiently. This type of thinking during the war led clinicians to attempt almost every conceivable modification in treatment in the hope of obtaining curative results. Such attempts, nevertheless, even with inordinately large amounts of drug used over prolonged periods failed appreciably to modify the course of the disease.

What then is wrong with this concept? It is simply that the cycle of the parasite in the human host is almost certainly far more complicated than the simple version on which clinicians in the past have relied. The modern view emphasizes that after the inoculation of sporozoites, invasion of endothelial cells or other fixed tissue cells takes place. Within these cells it is thought likely that the parasites undergo a distinct cycle of development before they are discharged into the blood stream, there to begin the so-called erythrocytic cycle.

---

[2] Activity of a New Antimalarial Agent, Chloroquine (SN-7618), Board for the Coordination of Malarial Studies, J. A. M. A. **130:** 1069 (April 20) 1946.

An essential part of this modern version is the postulate that persistency of infection and malarial relapse are closely linked with the cyclic development of parasites in the fixed tissue stage. Thus, the essential mechanism of relapse is conceived to result from periodic discharges of tissue forms into the blood stream. The persistency of an infection, on the other hand, is an expression of the length of time during which the development in fixed tissues continues. If this is true, it is clear why the P. falciparum and the P. vivax types of malaria are so different both in regard to the rate of relapse and the length of infection. A short period of development in the fixed tissue stage plus complete expulsion of all the parasites would lead to a short term infection without relapse. This, indeed, is characteristic of malaria due to P. falciparum. Conversely, a prolonged period of fixed tissue development with repeated partial expulsion of parasites would lead to a relapsing disease, and to its termination only when all the parasites were expelled. This, in general, characterizes infections due to P. vivax. Finally, if fixed tissue development differs in various strains of one species, different clinical patterns will follow. Such differences are exhibited by South Pacific and American strains of P. vivax and on the basis of this concept become readily understandable.

A most significant corollary to the modern concept is that which relates to therapy. Antimalarial drugs act principally, and usually almost exclusively, either on forms of the fixed tissue stage or on parasites in the erythrocytic phase. For example, quinine, quinacrine hydrochloride and chloroquine are known to act on the latter. Pamaquine, Paludrine and pentaquine act principally on the fixed tissue forms. With this knowledge it can readily be seen why quinacrine hydrochloride, which belongs to the former group of drugs, fails to cure benign tertian malaria. It can eradicate parasites in the red cells, but if relapse is a function of the fixed tissue phase, on which the drug is without effect, cure cannot be obtained. In contrast, it becomes evident why such a drug as pamaquine is curative, since the drug is capable of destroying fixed tissue forms and thereby eliminates relapses.

Unfortunately, conclusive evidence of a fixed tissue stage in man has yet to be demonstrated. There is, nevertheless, much to support the postulation of its existence. Such a stage has already been demonstrated by Huff[3] and others in several types of avian malaria. Recently Fairley[4] has shown in transfusion experiments in human volunteers that sporozoites disappear from the blood stream within thirty minutes after mosquito inoculation. On the seventh day in infections due to P. vivax and on the ninth day in those caused by P. falciparum he found that the parasites reappear in the circulation with remarkable regularity. The preciseness with which the parasites reappear strongly indicates that in some fixed tissue of the body a uniform, periodic cycle of development is taking place. Such evidence as this, plus the actual demonstration of an exoerythrocytic stage in birds, leaves little doubt that final proof of a similar stage in man will be forthcoming.

Despite the fact that the modern version of a preerythrocytic cycle of parasitic activity in the human host is as yet unproved, the experience of war years virtually forces its general acceptance. It explains differences in species and in strains and peculiarities of therapeutic response which formerly were left unexplained. It has passed from the stage of being an abstract concept of only passing interest to that of being one essential to the clinical management of malarial infections.

PREVENTION AND CONTROL OF MALARIA

In regard to measures which relate to the prevention of malarial infections and to basic procedures of control, war time experience and research have made important contributions in the following respects: (*a*) more effective anopheline control by the advent of DDT (4,4′-dichlorodiphenyltrichloroethane); (*b*) more effective drug prophylaxis as a result of the development of new drugs and improved methods in the use of drugs which formerly produced only mediocre results, and (*c*) renewed emphasis on the fact that effective malaria control is attained only to the extent to which organized methods are employed and carried out by a team of specialists.

Role of DDT.—Prior to World War II, the main attack on anophelines was almost solely confined to measures which would destroy larval forms. Measures against adult mosquitoes were difficult and infrequently attempted. With the introduction of DDT, however, the attack has become twofold, i. e., against both larvae and adults.

In the attack against the larval stages, the advantage of DDT has been found to rest principally in the efficaciousness of light applications. For example, 2 quarts per acre of a 5 per cent solution of DDT in diesel oil will now suffice to accomplish as effective a kill as that previously obtained by 20 to 40 gallons of oil without DDT. These light applications thus enable an important saving of oil, of time and of labor to be effected.

Where there are large areas to cover, airplanes have proved effective for the dispersal of DDT. In the extensive trials conducted during the war, different types of planes were used, varying from the small cub plane which would carry only 27 gallons to large multimotored transport planes with a capacity of many hundreds of gallons. These wartime trials indicate that the airplane in the postwar period will serve as an important aid to malaria control, not only as a device for saving time and labor but also for the control of areas otherwise inaccessible.

In the use of DDT to control adult mosquitoes, many promising possibilities are being explored. During the war military forces found that by impregnating bed nets, by spraying the inside of tents and other types of housing and, particularly, by spraying native quarters a significant reduction of the adult mosquito population could be accomplished. The attack on adult mosquitoes means that malaria transmission in an uncontrolled area can be stopped far more readily than has ever before been possible. No longer is it necessary to wait for the natural mortality of infected adult insects, as was formerly the case when the attack was made exclusively against larvae. Even more promising are current experiments in which complete control is being attempted solely by adult kill. Such experiments, it is hoped, will prove that whenever larvicidal measures are impractical for reasons of cost or inaccessibility, effective control by adult eradication can nevertheless be achieved.

This kill of adults is accomplished by the prolonged residual action of DDT. Another method of kill developed during the war is the use of aerosols containing

DDT. Under favorable conditions, these aerosols are capable of killing both adult mosquitoes and larvae in a single operation. The method represents an important lead which may prove of value in the control of malaria in civilian communities.

Repellents.—A great deal of wartime research was directed toward the development of new repellents. Unfortunately, repellents at present appear to have so many limitations that their general usefulness for protection against malaria does not seem promising. It is difficult to be certain that persons will use repellents regularly enough to afford any real degree of protection. In fact, a general principle learned during the war was that any measure of malaria control which relies on individual initiative is usually ineffective. Another inherent limitation to the use of repellents is that those which are effective against one species of mosquito frequently are largely without effect against another. Despite these limitations, present day repellents are vastly superior to those used in the past. In the future, persons who will take the trouble to use them will benefit thereby.

Drug Prophylaxis. — Wartime experience and research has greatly extended the usefulness of drugs for prophylactic purposes. It is now possible for military forces to operate in highly malarious, uncontrolled areas without significant malarial morbidity.

During the war, early results obtained with drugs were poor because of insufficient knowledge regarding their capabilities. As an example, rates at Guadalcanal, with all troops supposedly on suppressive treatment, soared to over 1,700 per thousand per annum. It is now known that these rates were unnecessarily high. They were a reflection of the misuse of drug prophylaxis.

The proof of this misuse came later as a result of a series of revealing investigations in the United States, Britain, Australia and elsewhere. These demonstrated that: (*a*) both quinacrine hydrochloride and quinine are fully preventive against malaria due to P. falciparum merely by prolonging the administration of the drug for approximately a month after the last exposure; (*b*) in malaria due to P. vivax these drugs are capable merely of suppressing clinical symptoms, and that overt attacks are inevitable when administration of the drug ceases; (*c*) quinacrine hydrochloride is superior to quinine as a suppressive, and (*d*), the mechanism of protection is not due to a destruction of infective organisms but to the reduction of parasitemia to a level insufficient for the production of clinical symptoms.

Carefully controlled human experimentation has further shown that various factors, such as combat fatigue or any other type of hard physical exertion, extreme cold, anoxia, blood loss and other factors do not precipitate "clinical break-throughs" in persons taking a drug as a suppressive measure. It has been definitely proved that failures with quinacrine hydrochloride which is taken in the recommended suppressive dosage are extraordinarily rare. Clinical break-throughs in troops are now known to be due to failure to take the drug, in the vast majority of cases.

This knowledge gained during World War II has important implications in the present day control of malaria in civil communities. As an example, labor forces working in highly endemic areas can carry on their work effectively to the extent that it is possible to insure that each member of the group takes the prescribed doses of quinacrine hydrochloride. Where malaria due to P. falciparum is prevalent, complete protection will be afforded. With infections due to P. vivax, the eventual problem of curing infections which have been temporarily suppressed must be faced when suppression by means of the drug is discontinued.

New Drugs.—Quinacrine hydrochloride has the serious drawback of staining the skin. In addition, many persons, on initial administration of the drug, experience gastrointestinal symptoms. For this reason, plus its inability to render any more than temporary protection in malaria due to P. vivax, attempts have been made to find other drugs which would not have these shortcomings. In this respect, chloroquine, recently developed, has the advantage that it will not stain the skin, nor does it so commonly lead to gastrointestinal symptoms as does quinacrine usage. Another advantage is that it needs to be administered only in a single weekly dose. This is exceedingly important, as careful supervision of weekly administration is much more feasible than the daily supervision required in the use of quinacrine. Chloroquine, like quinacrine hydrochloride, permits suppressive cure in infections due to P. falciparum and affords only temporary protection against malaria due to P. vivax.

This partial protective effect means that the important need of producing a fully protective drug against infection due to P. vivax has yet to be fulfilled. Some progress seems to have been made toward this objective with Paludrine. It has been shown that this drug, in malaria caused by P. falciparum, is capable of preventing infection, i. e., acts as a true causal prophylactic. Preliminary experiments against the infections due to P. vivax to date indicate that it exerts at least a partial causal prophylactic effect and does so in doses which appear to be nontoxic.

Entomologic Control.—Early in 1942, in the New Hebrides, the first large scale American occupation was followed by a 60 per cent malarial incidence in certain units during the first sixty days after arrival. A year later, malaria was no longer a major problem. By the following year, measures of control had been so successful that the appearance of a single primary case of malaria was viewed as a matter of concern. These dramatic results were achieved despite the prediction of the islands' residents that malaria control was impossible to effect and that every member of the military forces inevitably would acquire the disease.

The striking reduction in the incidence of malaria was not a result of new and revolutionary methods. It was simply the product of organized efforts applied by trained personnel. In this respect the key person probably was the entomologist. For example, on Efate, prior to organized efforts by trained personnel, the island had been surveyed by inexperienced workers. As a result, control efforts were centered on the removal of half shells from the extensive coconut plantations, since these shells appeared to be prolific sources of mosquitoes. The attempt to gather and burn coconut shells constituted a measure requiring enormous effort. With the arrival of the entomologist, it was soon determined that the vectors of malaria did not breed in coconut shells. In contrast, in the margins of several small streams not previously investigated, anophelines were found breeding profusely. It was a far simpler task to control breeding on these few streams. Results in reduced malarial incidence were soon forthcoming; however, had the original approach been continued, not a single anopheline larva would have been killed, nor would a single case of malaria have been averted.

While the entomologist was a key person in that his training enabled him to locate the single species transmitting malaria and to concentrate efforts on that species, the rapidity with which control was achieved was actually the expression of teamwork on the part of various workers. Thus, in addition to the entomologist, a malariologist directed the overall program and an engineer carried out control operations.

Malaria control not only succeeded on Efate but also met with similar success on the many other islands of the South Pacific where specialists and organized methods were employed. The present day significance of these wartime achievements in the control of malaria is that they reemphasize the fact that a like approach in civilian communities is essential. With such methods, according to Russell,[5] "One may reasonably hope that, with suitable organization, malaria will be eradicated from the United States within the next decade, and that in many tropical areas, even though economically depressed, this disease, now of the greatest importance, may become in the next half century one of the least of public health problems."

ANASTOMOSIS OF THE AORTA TO A PULMONARY ARTERY

Certain Types in Congenital Heart Disease

WILLIS J. POTTS, M.D.
SIDNEY SMITH, M.D.
and
STANLEY GIBSON, M.D.
Chicago

In 1945 Blalock and Taussig[1] introduced a new surgical procedure for the relief of anoxemia due to pulmonary stenosis or pulmonary atresia. By anastomosing the subclavian or innominate artery to either the right or the left pulmonary artery they have been able to increase the flow of blood to the lungs. Their work is an outstanding contribution to the relief of children whose outlook without aid is hopeless. Sacrifice of the subclavian artery for the anastomosis of its proximal end to the side of a pulmonary artery is associated with little danger to the circulation of the arm. Use of the innominate artery for such an anastomosis entails the hazard of an inadequate supply of blood to the brain.

The possibility of making a direct anastomosis between the aorta and the adjoining pulmonary artery was reviewed. Gross and Hufnagel[2] and Blalock and Park[3] concluded from their experimental work on animals that clamping off the aorta completely for any considerable length of time leads in a fair percentage of experiments to paralysis of the hind legs caused by temporary anemia of the spinal cord. An anastomosis, therefore, between the aorta and the pulmonary artery can be performed safely only if a substantial amount of blood is flowing through the aorta during the procedure. This was made possible by the use of a new type of clamp which two of us have designed (W. J. P. and S. S.), which is illustrated in figure 1. The two flanges of this clamp encircle the aorta and, when closed, pinch off a small but sufficiently large portion of the aorta to allow room for an anastomosis. The major portion of the aorta lies in the hollow of the clamp and rests against it. Since each pulsation of the enclosed aorta is transmitted to the back of the clamp with the same force as that which acts against the portion of the aorta which is occluded, there is no tendency for the clamp to slip off. It is unnecessary to tighten the clamp beyond simple occlusion. When the clamp is closed the lumen of the aorta is reduced to approximately half its size.

Other instruments which we developed or designed for the aortic pulmonary anastomosis are illustrated in figure 2.[4]

The details of aortic pulmonary anastomosis were worked out on approximately 30 dogs. This operation could not have been performed successfully on the human being without preliminary work on animals. Although the experimental work will be reported later, it is pertinent to state here that none of the animals showed any postoperative paralysis of the hind legs.

TECHNIC

Aortic pulmonary anastomosis has been performed on 3 children. Although there were slight variations in each operation, the technic in general was as follows:

Cyclopropane and oxygen anesthesia was used. In an operation of this type expert anesthesia is essential. This was given by Dr. Wm. O. McQuiston.

A cannula was inserted into the saphenous vein at the ankle for the continuous administration of plasma and for the emergency administration of blood. The child was placed on its right side with the left arm abducted and fastened to the anesthetic shield. A curved incision was made below the left scapula from the edge of the erector spinae muscles to the nipple line (fig. 3 *A*). The chest was entered by an incision through the fourth interspace, and adequate exposure was obtained with a ribspreader. The collapsed upper lobe of the lung was displaced from the operative field by a wet laparotomy pad.

The left pulmonary artery was identified and freed from surrounding structures by blunt dissection. Small tortuous veins overlying the artery were tied and cut. The artery was occluded for two minutes to determine whether the right pulmonary artery alone would carry sufficient blood to support life during the time required for the anastomosis. Detectable changes in color, pulse rate, respiratory rate and blood pressure were not observed in any case. The aorta was then dissected from its bed. With scissors an incision was made through the reflection of the parietal pleura over the lateral surface of the aorta, just distal to the arch. The vagus nerve was identified in its position between the aorta and the pulmonary artery and displaced posteriorly. The intercostal arteries arising from that portion of the aorta to which the clamp was later to be applied were doubly ligated with silk and cut between the ligatures. Two silk ligatures were placed around the pulmonary artery, each encircling the vessel twice. One was placed as far distally as possible, the other as far proximally as possible (fig. 3 *B*). The pericardial sac

[4] These instruments and the clamp shown in figure 1 were made for us by V. Mueller and Co., 408 South Honore Street, Chicago.

was not opened. The clamp was then applied to the aorta and slowly closed (fig. 3 *C*). In each patient after the clamp was closed a thrill was palpable distal to the clamp, indicating that blood was rushing through the constricted aorta. If a section of aorta sufficiently large for anastomosis did not protrude beyond the flanges of the clamp as it was closed, the adventitia of the aorta was grasped and enough of the aorta drawn out to make suture technically possible. The adventitia was dissected only from that portion of the aorta protruding from the clamp. With an extremely sharp, small-blade knife a longitudinal incision 5/16 to 6/16 inches (8 to 9.5 mm.) long was made in the clamped-off portion of the aorta. While this incision was being made the rounded wall of the aorta was flattened by pressure with the spread prongs of a tissue forceps. Unless the wall of the aorta is cut squarely, the edges have a tendency to fray. The two ligatures doubly encircling the pulmonary artery were tied to the corners of the clamp, thus simultaneously occluding the vessel and alining it with the aorta for anastomosis. Opposite the incision in the aorta an incision of similar size was made in the occluded pulmonary artery. This incision was made slightly diagonal so that at completion of the anastomosis the vessels in assuming their normal relationship would not produce a kink in the pulmonary artery (fig. 3 *D*).

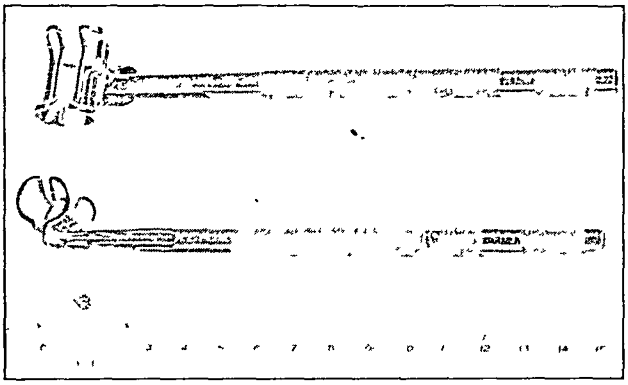

Fig 1.—Clamp for anastomosis of the aorta to a pulmonary artery.

The anastomosis was done with no. 5 Deknatel silk on a no. 9 curved atraumatic needle. The suture, beginning at the upper angle, was carried through the pulmonary artery from the outside in, then across through the aorta from the inside out—and tied (fig. 3 *E*. This brought the knot outside the vessels. In continuation of this suture, the posterior lip of the pulmonary artery was sewed to the posterior lip of the aorta by a running, over and over stitch. These stitches, approximately 1 mm. apart, included all layers of both vessels. In this portion of the anastomosis adventitia was brought to adventitia. At the lower angle of the wound the suture was locked and then continued as a running suture, bringing the anterior lip of the pulmonary artery to the anterior lip of the aorta, intima to intima. The long end of the suture was tied to the short end to complete the anastomosis. The ligatures holding the pulmonary artery to the clamp were cut, first the distal, then the proximal. The aortic clamp was then slowly released and removed. In no instance was there enough bleeding to require additional sutures. In each patient the thrill of blood flowing through the new opening could be felt.

The lung was reexpanded, and the incision in the chest was closed with three chromic gut sutures encircling the adjoining ribs. The muscles were reunited, and the skin was closed with silk.

REPORT OF CASES

We shall not undertake a discussion of the criteria for diagnosis of the tetralogy of Fallot. These criteria have been set forth by Blalock and Taussig, and we have attempted to select our cases in accordance with the principles which they have laid down.

Case 1.—*History and Examination.*—D. S., a girl, born Dec. 10, 1944, weighing 6 pounds and 10 ounces (3,005 Gm.), appeared to progress normally until she reached the age of 3 months. At that time the mother observed that the baby became blue around the lips during her feeding and seemed quite limp at the conclusion of her meal. The cyanosis increased gradually in intensity, was particularly noticeable after feeding, crying or fretting and eventually was observed even when the infant was at rest Dyspnea became evident as time went on Finally her condition became so poor that feeding was a serious problem. If she were fed a little too much or took her food too rapidly she became extremely cyanotic and limp, her eyes became fixed, and she lapsed into unconsciousness On two occasions the mother thought that the child was dead. The entire household was organized with the single thought of contributing to her comfort. Her 3 year old brother was kept from her room, and neighboring children were not allowed to play in the house

Though the child had sat up at 6 months, she had never walked or stood alone. She had gained slowly in weight

She was first seen by us on Sept. 9, 1946 at the age of 21 months. Her weight at that time was 18 pounds 4½ ounces (8,291 Gm.). She was intensely cyanotic. The fingers were clubbed. Examination of the heart revealed a harsh systolic murmur along the left sternal margin The roentgenogram did not show enlargement of the heart. The heart appeared to sit high on the diaphragm, and the apex was blunt and rounded. There was a concavity in the region of the pulmonary cone. The aorta could be seen in its normal position. Fluoroscopic examination failed to show pulsations in the pulmonary arteries. The electrocardiogram showed axis deviation to the right. The red blood cell count was 10,310,000 per cubic millimeter, the hemoglobin level was 18 6 Gm Because

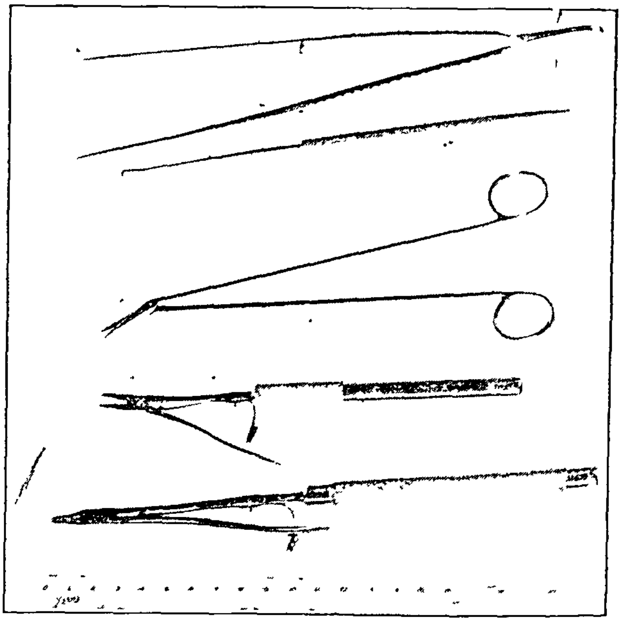

Fig. 2.—Essentially standard instruments modified to work in a small, deep cavity.

of the patient's critical condition, oxygen saturation studies of the arterial blood were omitted. We believed that she presented the typical picture of a severe case of the tetralogy of Fallot.

Operation.—The operation was performed on Friday, Sept. 13, 1946. Cyclopropane anesthesia with a high concentration of oxygen was given by the closed method with a snugly fitting face mask. The child's color improved greatly at the beginning of anesthesia and remained good throughout the operation.

Fig. 3.—Technic of operation: *A*, incision; *B*, ligatures around pulmonary artery; *C*, clamp applied to aorta, and *D*, diagonal incision of occluded pulmonary artery, and *E*, the suture.

The left pleural cavity was entered posteriorly through the third interspace. The incision was too high. Adequate exposure was not obtained until the fourth, fifth and sixth ribs were cut along the erector spinae muscle. The pulmonary artery was identified and exposed without difficulty. Small, tortuous, dilated veins lying on the pleura over the aorta were tied and cut. On lifting the aorta from its bed, we observed an unusual number of small arteries, at least a dozen, arising from that small portion of the aorta where the clamp was to be applied. Some of them were intercostal arteries, and the rest presumably were vessels which had dilated in response to a demand for collateral circulation to the lung. Isolating, ligating and cutting these vessels was the most tedious and time-consuming part of the operation.

Since the pulmonary artery lay in the same plane as the aorta, the incision in it was made parallel with its longitudinal axis. The actual anastomosis was performed without difficulty and required twenty-three minutes. When the clamp was removed a palpable thrill could be felt in the anastomotic channel. The chest was closed. The total operating time was three hours.

The blood pressure at the beginning of the operation was 95 systolic and 60 diastolic; at the close of operation it was 100 systolic and 60 diastolic. When the clamp was tightened on the aorta, the systolic blood pressure rose 10 points but in a few minutes returned to its previous level. The pulse rate remained practically constant throughout the operation at 120 to 132 beats per minute. The patient received 200 cc. of plasma during the operative procedure.

Postoperative Course.—The infant was brought to her room in good condition. She received 100,000 units of penicillin in the plasma which was being administered by vein. Thereafter she received 30,000 units of penicillin every three hours for ten days. In the first twenty hours following operation she received 200 cc. of 5 per cent dextrose in isotonic solution of sodium chloride and 625 cc. of a solution of 10 per cent dextrose in water. Her postoperative course was remarkably smooth. She was kept in an oxygen tent for three days. Vomiting did not occur. She began taking fluids twenty-four hours after operation and was given a soft diet on the following day. The lungs remained clear. Examination of the heart revealed a slight carry over of the murmur into diastole, though it was not comparable to the harsh continuous murmur which one hears in the typical patent ductus. The most striking change was in her color and in her general behavior. She took her food without difficulty; when disturbed by her doctors she cried for several minutes without turning blue, and in the intervening time she was happy and playful. She gained a pound (454 Gm.) in the first eleven days after operation

On the third day following operation her red blood cell count was 6,600,000 per cubic millimeter, hemoglobin content 14.3 Gm. and hematocrit reading 44. Subsequent counts at three day intervals gave substantially the same results. She was discharged from the hospital on October 2, nineteen days after operation. A later note from the mother states that the baby's condition is excellent, and that her color compares favorably with that of the other children who now come in to visit her.

Case 2.—*History and Examination.*—G. M., a girl, born Jan. 21, 1935, made her first visit to our outpatient department at the age of 14 months because of inabiltiy to move her left arm and leg during the previous three days. Examination at that time revealed slight generalized cyanosis with a deeper color about the gums, lips and fingertips. A systolic murmur was heard over the precordium, maximal in the second and third interspaces on the left side along the sternal margin. A thrill was palpable. A left hemiparesis was present. The deep reflexes on the left were increased. Ankle clonus and positive great toe reflex were present. The diagnosis at that time was congenital heart disease complicated by cerebral thrombosis. She was seen at intervals in the outpatient department. She became gradually more cyanotic, was very late in walking, and her mental progress was slow.

She was admitted to the hospital on Sept 5, 1946, at the age of 11 years and 8 months. She was a small, thin child, weighing 54 pounds (24.5 Kg.). The left arm and leg were smaller than the right, with some spasticity due to the cerebral accident which had occurred in infancy.

The entire skin was cyanotic with intense cyanosis about the eyes, lips and tips of the fingers and toes. Clubbing of the fingers and toes was well defined. Psychometric examination established her intelligence quotient at 66. Cardiac examination failed to reveal any enlargement. There was a short, harsh systolic murmur, best heard in the second and third interspaces on the left side and not widely transmitted. The roentgenogram showed slight cardiac enlargement, with a blunt, rounded apex. There was a concavity in the region of the pulmonary conus. Under the fluoroscope a pulmonary window was seen but pulsations were not observed in the pulmonary arteries. The electrocardiogram showed well defined axis deviation to the right. The red blood cell count was 10,190,000 cells, the hemoglobin level 26.5 Gm. and the hematocrit reading 79. The oxygen saturation of the arterial blood was 38.7 per cent.

Operation.—The operation was performed on September 16. Under cyclopropane and oxygen anesthesia the intense cyanosis did not improve appreciably.

There was persistent and troublesome bleeding from the severed muscles of the chest wall. The left pleural cavity was opened through the fourth interspace, and adequate exposure was obtained without cutting any ribs. Each time the upper lobe of the left lung was retracted there occurred a "bronchial spasm" which made it momentarily impossible to force oxygen into the lungs with a pressure bag. After repeated episodes, it became obvious to the anesthetist that the administration of intratracheal anesthesia was necessary. Because of the extreme anoxia it was necessary to close the chest and reexpand the lung before the intratracheal tube could be introduced safely. Under intratracheal anesthesia the operation was resumed.

The hilus of the left lung was covered with a mass of tortuous veins black with cyanotic blood. The pulmonary artery was exposed and isolated with great difficulty. Any tiny vein accidentally torn oozed tarry blood, which obscured the field. The aorta was easily freed. Five intercostal arteries were doubly tied and then cut to make room for the clamp. Too rapid closure of the clamp on the aorta resulted in a rise in the systolic blood pressure from 100 to 132. The clamp was released, and the blood pressure returned to 100. When the clamp was closed more slowly the systolic blood pressure rose to 110 mm. and remained at that level throughout the anastomosis. On completion of the anastomosis, a thrill was palpable but was less intense than in the previous patient. The actual anastomosis required forty-five minutes. During the operative procedure the child received intravenously 100 cc. of isotonic solution of sodium chloride, 200 cc. of whole blood and 300 cc. of plasma.

Postoperative Course.—The patient was in poor condition when returned to her room. She was placed in an oxygen tent, and 100,000 units of penicillin was administered in the intravenous fluids. Subsequently 30,000 units of penicillin was given intramuscularly every three hours. She roused slightly several hours after operation, and it was then observed that she failed to use her right arm and leg. She remained in a semiconscious state. On the morning after the operation her color was distinctly improved. Some hours later she became dyspneic, and coarse moist rales were heard throughout the chest. Supportive treatment was ineffective, and she expired at 8:00 p. m. on September 17, thirty-six hours after the operation.

Postmortem examination revealed that the anastomotic channel was open. Leakage had not occurred. There was a small thrombus in the left pulmonary artery proximal to the site of anastomosis. The pleural cavity was dry. Thick mucopurulent secretion was present in the trachea and bronchi. The lungs were congested. A scar was found in the right frontoparietal region of the brain, obviously the result of the cerebral accident which the patient suffered at the age of 14 months.

On the left side a hemorrhagic infarct occupied the upper portion of the postcentral gyrus.

CASE 3.—*History and Examination.*—B. K., a girl, born Aug. 5, 1938, weighing 6 pounds, 8¾ ounces (2,969 Gm.), was first seen in the outpatient department at the age of 3 weeks, at which time she had a loud systolic murmur over the precordium, maximal at the third interspace on the left side. There was no cyanosis. A tentative diagnosis of defect of the interventricular septum was made. When the infant was seen on March 8, 1939 at the age of 7 months, the mother reported that the baby became breathless when a large amount of food was taken at one time. On Sept. 30, 1939 examination revealed cyanosis on crying and slight clubbing of the fingers. She was then lost to the clinic until Aug. 11, 1945. At that time she was definitely cyanotic and tired easily on exertion. She had grown slowly and weighed only 27½ pounds (12 Kg.) at the age of 7 years.

She was admitted to the hospital on Sept. 21, 1946. The mother stated that the child had recently been able to exercise less than formerly and would squat down to rest after walking half a block.

Physical examination revealed a small, slender child who was decidedly cyanotic, with suffusion of the eyes and clubbing of the fingers. Her weight was 29½ pounds (13 Kg.).

There was a harsh systolic murmur over the precordium, best heard on the left along the sternal margin at about the third interspace. Roentgenologic examination showed the heart to be slightly enlarged with a rounded blunt apex and without fulness in the region of the pulmonary cone. The aortic knob was visible to the left of the sternum. In the left anterior oblique position the pulmonary window seemed to visualize well. The electrocardiogram showed decided axis deviation to the right. The red blood cells numbered 9,880,000 per cubic millimeter, the hemoglobin content was 24.8 Gm. and the hematocrit reading was 67.

Operation.—The operation was performed on September 27. Intratracheal cyclopropane and oxygen anesthesia was administered by Dr. Wm. O. McQuiston. The patient's color was much better under anesthesia than it had been previously.

The left pleural cavity was entered through the fourth interspace posteriorly, and adequate exposure was obtained with a ribspreader. The pulmonary artery was easily separated from surrounding structures. That portion of the aorta immediately distal to the arch was exposed. Six intercostal vessels required ligation. One of them was at least 2 mm. in diameter. The blood pressure remained unchanged during slow closure of the clamp on the aorta.

Incision in the pulmonary artery was made at an angle so that on completion of the anastomosis the vessels lay in normal relationship to each other without kinking the pulmonary artery.

The pulmonary artery was rather large and consequently wrinkled by the two encircling, holding ligatures. The bite taken in suturing the anterior lip of the pulmonary artery to the anterior lip of the aorta was too large. When the anastomosis was completed and the clamp removed, some constriction of the pulmonary artery was apparent. While this probably made little difference in the flow of blood through the pulmonary artery, it was a technical error. A palpable thrill could be felt in the anastomotic channel. The lung was reexpanded and the chest closed. The child received 300 cc. of plasma intravenously during the operative procedure. Her condition at the close of the operation was excellent. The operative time was two hours and forty minutes.

Postoperative Course.—The patient was returned to her room in good condition. She was placed in an oxygen tent. One hundred thousand units of penicillin was given in the intravenous fluids which she received following operation, and 30,000 units of penicillin was given every three hours for fourteen days postoperatively. On the evening of the operation she took sips of fluid, and on the next day she received a soft diet. Her condition was good. On September 30 it was noticed that dulness and diminished breath sounds were present over the left side of the chest. Inasmuch as the child seemed comfortable paracentesis was not performed. However, the signs in the chest gradually increased, and on October 3 she appeared tired but was not distinctly dsypneic. A chest tap was performed, and 240 cc. of grossly bloody fluid was removed. From this point on, recovery has been uneventful and the roentgenogram reveals that the chest has cleared. At the present writing, seventeen days after operation, she is walking freely about the ward. She has only a slight cyanotic tinge. She requests second helpings at each meal. She has gained 4 pounds (1.8 Kg.) since the operation.

On the third day following operation, her red blood cell count was 6,640.000 per cubic millimeter, the hemoglobin content 18.6 Gm., and the hematocrit reading 50.5. Subsequent examinations gave essentially the same results. The oxygen saturation of the arterial blood on October 11 was 77 per cent. The heart was examined daily following operation, and we were somewhat disturbed by the fact that the murmur seemed to be identical with that which had been heard previously. When the dressings were completely removed, however, a soft but distinct diastolic blow in addition to the systolic murmur was audible.

COMMENT

One of the possible advantages of this operation lies in the fact that we are free to make the anastomotic channel whatever size seems proper. Only years of experience and observation will determine the answer to that question. Thus far we have been guided by the work of Blalock and Taussig and have attempted to make the openings approximately the size of either the innominate or the subclavian artery. It may be that an additional field of usefulness of this operation will be in younger children in whom it is desirable to avoid sacrifice of the innominate artery.

In the first child, aged 21 months, the incision in the aorta measured $\frac{5}{16}$ inch (8 mm.); in the other 2 children, aged 8 and 10 years, respectively, the incision measured approximately $\frac{6}{16}$ inch (9.5 mm.). These figures do not represent the diameter of the anastomotic channel. An 8 mm. cut in a vessel will produce on expansion of that vessel an opening approximately 5 mm. in diameter, and a 9.5 mm. cut will produce an opening slightly less than 7 mm. (Formula: Length of the incision $\times 2 \div 3.1416 =$ diameter of the opening.) Will the anastomotic channel enlarge as the child grows, or will it remain fixed? Work has been planned to answer this question. At present it seems logical to gage the size of the opening by the age, weight and degree of anoxemia of the patient.

Vascular surgeons agree that it is desirable to suture all vessels intima to intima. However, from our experimental evidence we do not believe that in aortic pulmonary side to side anastomosis the complex technic of suturing intima to intima in the posterior row of sutures is necessary or desirable. Bleeding is less apt to occur from such a suture line between vessels which are opposed adventitia to adventitia. This fact is important in an anastomosis in which the posterior row of sutures is inaccessible after the anterior row has been completed. In 30 anastomoses on dogs and 3 on children bleeding from the posterior suture line was not present. Furthermore, we have found that intra-aortic pressure tends to oppose the inverted lips of the posterior row of sutures, leaving an almost negligible gap between the intimal edges. It is true that a running over and over stitch opposing adventitia to adventitia does expose more suture material to the flow of blood. This does not violate the principles of vascular surgery (Smith[5]).

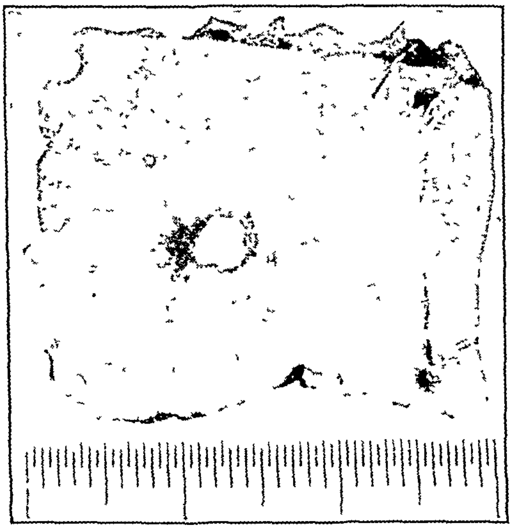

Fig 4—Anastomotic channel between aorta and left pulmonary artery from a dog eighty one days after operation, the aortic side

The suture material and the anastomotic margins are covered with a layer of endothelium within twelve to twenty-four hours (Carrel and Guthrie,[6] Smith[7] and Horsley[8]). To date, in none of the animals which we have killed from one to eighty-one days following aortic pulmonary anastomosis have we found more than pinhead sized thrombi on the suture line. In fact, the anastomotic lumen of the dog killed after eighty-one days was entirely free from thrombi, and the silk was deeply covered with endothelium (figs. 4 and 5).

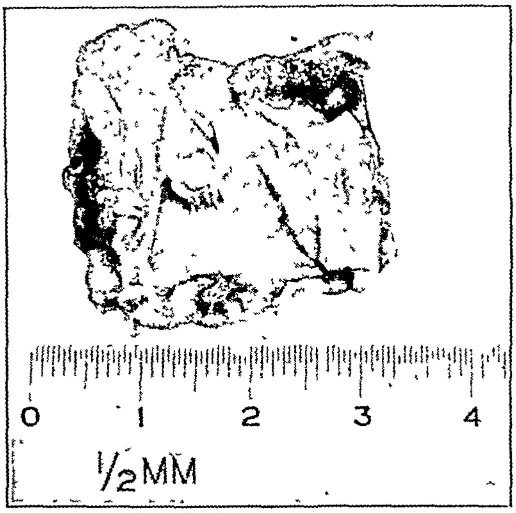

Fig. 5.—The pulmonary side of anastomotic channel in figure 4.

CONCLUSION

Only because we were backed by the fundamental principles set forth by Blalock and Taussig for the surgical relief of anoxemia in certain types of congenital heart disease did we have the courage to attempt this new operation. The operation is not a simple one. In attempting this new procedure it seemed only fair to choose those patients whose condition was such that without aid their future was hopeless. The 2 children who survived the operation have been tremendously benefited.

Epidemic Hepatitis.—During this war epidemic hepatitis has attained pandemic proportions. Large outbreaks have occurred in many parts of the world and in the armies of a number of nations The pathology of this disease as observed in the Army of the United States during the epidemic of 1942 has been dealt with in previous papers More recently an acute form of epidemic hepatitis of intense severity terminating fatally in less than ten days has become prevalent; this we have termed the fulminant form In a new series of 196 fatal cases occurring between August 1943 and April 1945 which we have studied at the Army Institute of Pathology, over half fall into this category By contrast, in the previous series not a single equally fulminant case was encountered, and only 1 was reported in the great Swedish epidemic of 1927; the usual duration of the fatal disease was then from four to six weeks; in other words, the course of fatal hepatitis was predominantly subacute. These divergences in duration reflect striking differences in the pertinent pathologic changes Thus, in the more fulminant form the parenchyma of the liver is destroyed completely and uniformly, and this destructive process is accompanied with an intense inflammatory reaction In the more subacute form seen in 1942 and also in about one fourth of the 1943-1945 series destruction of the liver is incomplete, the involvement characteristically not uniform, regenerative hyperplasis of surviving parenchyma leads to the production of much new tissue, and inflammation is less pronounced—Lucke, Balduin, and Mallory, Tracy: The Fulminant Form of Epidemic Hepatitis, *Am. J. Path.* 22:868 (Sept) 1946

CEREBROSPINAL CRYPTOCOCCOSIS

C. M. MEZEY, M.D., and ROGER FOWLER, M.D.
New London, Conn.

Cryptococcosis is a subacutely or chronically manifested infection caused by a yeast called Cryptococcus neoformans which may involve the skin, lungs, lymph nodes or other parts of the body but which has a decided predilection for the brain, meninges and spinal cord.

The disease is also called European blastomycosis, torulosis and Busse-Buschke's disease. The causative yeast has about fifty synonyms, of which the best known are: Cryptococcus neoformans, Vuillemin, 1901; Saccharomyces, Busse, 1894; Saccharomyces neoformans, Sanfelice, 1895; Cryptococcus hominis, Vuillemin, 1901; Torula neoformans, Weis, 1902; Torula histolytica, Stoddard and Cutler, 1916; Cryptococcus histolyticus, Castellani, 1928; Cryptococcus meningitidis, Dodge, 1935; Debaryomyces hominis, Todd and Herrmann, 1936; Cryptococcus farciminosus, Rivolta; Saccharomyces farciminosus, Tokushige, and Endomyces farciminosus, Eberbeck. The present accepted terminology of Cryptococcus neoformans is suggested by the National Research Council (Manual of Clinical Mycology).[1] All these synonyms are based on a botanic classification which is still subject to many controversies.

The appearance of the cryptococcus in infected material is the same as in blastomycosis. If the material is not examined promptly a contamination of saprophytic cryptococcus may be present also. According to the military medical manual of mycology, the cryptococci are differentiated from other fungi by their single bud and wide capsule and their failure to produce a moldlike growth at room temperature. No distinctive reproductive process can be discovered in any of the yeastlike organisms. They adapt themselves entirely to their culture mediums and their environment, which adaptation even causes genetic changes in them, according to Brumpt.[2] This type of fungus lacks a constant morphologic character, and the morphology depends entirely on the medium, age and temperature. In a fresh growth at room temperature on Sabouraud's heavy mediums it is impossible to differentiate the torula from the blastomyces. It is in older cultures in which the mycelium is vanishing that the differentiation may be possible, but as a rule the plate interpretation is confusing. The pathologic and clinical picture is essentially the same in both blastomycosis and cryptococcosis, the most striking identity being shown in the meningitic type of the disease.

For these reasons it would be advisable to give one clinical name to all diseases caused by yeasts instead of adhering to the botanic classifications.

In 1937 Levin[3] analyzed 60 well authenticated cases of the meningitic type. He found that the average duration of the disease is five or six months. The prognosis is extremely poor; in the case on record longest the patient lived for five and a half years. Its clinical course may resemble any other type of meningitis; yet the ease of demonstrating the yeast cells in the spinal fluid on direct examination makes the differentiation rather easy.

This disease occurs as a chronic one of solipeds and occasionally in cattle also, with a predilection for the lymph glands and lymphatic vessels. It is called epizootic lymphangitis. Benham[4] inoculated a saline suspension of the yeast intraperitoneally in mice. Lesions developed slowly. Gelatinous masses around the site of the injection and enlargement of the peritoneal nodes and brain tissue revealed the presence of the yeast.

In our series of mice inoculations, all the mice died within fourteen days and showed granulations containing yeast cells around the site of infection, but we have been unable to see distant metastases. The cause of death was apparently a rapidly developing toxemia.

No toxic products can be demonstrated in the cultures. No exotoxins or cutaneous hypersensitiveness are present, and agglutinins develop only in a low titer, no higher than 1:180 dilution. We believe that toxic products are formed in the body by the disintegration of free parasitic cells.

According to Hutyra,[5] an animal can be immunized in about fifty days, but until immunization takes place there is a hypersensitization present. The disease consists of a long chain of recurrences which show definite periodicity. They are released at intervals of eighteen to twenty-one days. Such periodicity can not be explained, unless the onsets are released by repeated reinfections or autoinfections. Complete recovery brings immunity. The road toward immunization is a series of attacks of lesser intensity. For practical purposes it seems safe to assume that if sixty days pass after the last recurrence and the patient shows signs of clinical well-being, he can be considered immune.

Martin and Smith[6] have used a complement fixation test in which the level of the antibody titer is used to indicate the degree of infection. A high antibody titer indicates an extremely unfavorable prognosis. A more favorable course can be anticipated when the complement fixation test is negative. However, we are unable to determine by this test whether or not immunity has taken place.

The source of the infection is unknown. Cases of human infection from animals have been reported occasionally; Negre[5] reported the case of a veterinarian who infected his thumb while operating on an infected horse. The veterinarian recovered after the intravenous injection of 6 Gm. of arsphenamine. Tokushige has reported several infections in China. The transmission of the infection by insects, according to Hutyra,[5] is principally only an incidental conveyance.

Cryptococcosis has been reported in children of less than 10 years of age and in adults of more than 70 years, but most of the cases occur in patients between the ages of 40 and 60. In a series of 60 cases of meningeal cryptococcosis 39 were men and 21 were women. All races are apparently equally susceptible.[1] There are relatively more cases reported in Algiers and China than in any other part of the world. The reason may be that the torulosis of horses is a common disease in these countries. To our knowledge there have not been reported any cases in which the disease was transmitted from man to man. Benham[4] showed that the pathogenic human strains differed morpho-

logically, serologically and pathologically from the animal strains; yet we know that any yeast will show the most unusual changes in its biology, depending on the mediums and age.

It is thought that the fungus enters through the respiratory tract because in almost every case of cerebrospinal cryptococcosis the history of the patient reveals a mild but definite respiratory infection. Isolated lesions have been reported in the skin, mucous membrane and subcutaneous tissues. The meningeal form of cryptococcosis is always caused by a local infection which spreads to the brain and meninges. Since no sudden onset appears, it is probable that continuous synergenetic sensitization has to be present until clinical types of the organism develop.

In regard to the differential diagnosis, laboratory examination of the spinal fluid or other infected bodily secretions will rapidly and in an easy way demonstrate the presence of yeast cells. These smears should be unstained and diluted with a drop of distilled water. The staining methods are of no advantage, often making recognition even more difficult. The india ink method of staining gave us poor results. Probably the reason for this is that the india ink obtainable now is full of impurities and not a colloidal suspension. Therefore, it will not differentiate the yeast cells from the surrounding field.

The roentgenologic diagnosis may reveal a shadow in pulmonary infections without the formation of a cavity. The mediastinum is rarely involved. Just the opposite picture is seen in actinomycosis. The increased intracerebral pressure in chronic cases may produce atrophic changes in the inner table of the bone, but the bone itself is not invaded. Yet the roentgenogram will give no clue in the early case in which diagnosis is most urgently needed. Since there is no convincing evidence concerning the allergic status in cryptococcosis, we do not see any justification for skin testing as a diagnostic procedure.

REPORT OF CASE

History.—A white city housewife aged 38 was admitted to the Lawrence and Memorial Associated Hospitals on Dec. 27, 1945, complaining of vague headaches, nausea, slight cough and generalized muscular pains.

The familial, marital and past histories were noncontributory. The environmental conditions were excellent.

For about nine months before admission the patient felt occasional occipital headaches, which were rather dull and occurred in periodic spells of two to three days' duration. These headaches gradually increased in intensity and were occasionally accompanied by nausea and vomiting. She had a slight chronic cough most of the time and expelled a small amount of grayish sticky sputum. She had not consulted a doctor for any of these symptoms, but had taken different medicaments for her headaches, none of which gave any relief.

Five days before admission she went to a carol-singing, where she was exposed to windy, cold weather. The next day severe muscular pains in the neck and posterior region of the shoulders developed, which forced her to go to bed. Her condition was diagnosed as acute myositis and she was treated accordingly. Three days later the pains spread to muscles all over the body and were especially severe in the muscles of the calves. There was continuous nausea followed by vomiting immediately after the ingestion of food. Fever was not present at any time, although the patient complained of severe chills at the onset. Active motion increased the muscular pains and motion of the head induced vomiting. A day before admission she seemed confused and drowsy.

Admission and Examination.—The patient was admitted in the hospital with a tentative diagnosis of acute myositis and cyclic vomiting due to a possible trichinosis. On admission her temperature was 98.6 F., her pulse rate 60, her respiratory rate 25, and her blood pressure 120 systolic and 65 diastolic. She gave the impression of being extremely ill and showed signs of meningism (stiff neck). The neurologic examination did not show any particular changes, nor was any remarkable change seen in other organs.

On account of the stiff neck a spinal puncture was obtained under normal pressure and about 6 cc. of reddish spinal fluid was withdrawn. The laboratory examination revealed a decided xanthochromia, Pandy's test showed a trace of globulin; sugar was 27.5 mg. per hundred cubic centimeters and there were 5 lymphocytes. On counting the cells the technician observed the presence of numerous small cells resembling, but smaller than, the usual red cell. Under close examination these cells showed the typical morphology of yeast. A culture was made on Sabouraud's medium and after ten days a growth was obtained which has been identified as Cryptococcus neoformans. Other laboratory studies on the blood showed a hemoglobin content of 14.2 Gm. per hundred cubic centimeters, 4,770,000 red blood cells and 5,950 white blood cells, with 45 lymphocytes, 1 monocyte, 50 polymorphonuclears with 5 nonsegmenters and 4 eosinophils. Urinalysis revealed an acid reaction, a specific gravity of 1.025, a trace of albumin and a 4 plus reducing substance. The blood sedimentation rate by the method of Cutler showed a diagonal curve which reached 31 mm. in 60 minutes to indicate moderate activity. Roentgenograms of the chest showed increased bronchial markings but were otherwise negative.

Course at the Hospital.—The patient's temperature was flat, except for a moderate elevation of one or two days' duration at intervals of three weeks, corresponding to the exacerbation of the disease. Her course was one of steady improvement. Her muscular pains abated quickly, although dull headaches and nausea of varying degrees remained with her throughout her whole hospital stay. Weekly examinations of the spinal fluid revealed the constant presence of yeast, averaging about 20 yeast cells per millimeter. The patient was dismissed for ambulatory treatment on April 1, 1946.

In her home she resumed her housework and felt well except for occasional malaise and nausea during her periods of exacerbation. She gained 15 pounds (6.8 Kg.). The patient is not immunized as yet.

Treatment.—The treatment of this disease has proved unsatisfactory in the past. We believe that the danger lies in the toxic symptoms caused by the budding of the yeast cells, by which the toxins are most probably released. For this reason we tried a treatment which would "fix" the yeast cells and prevent the emanation of the toxins. To attain this we administered a continuous intravenous drip of 5 per cent alcohol, by which we hoped to obtain a 2 mg. blood level of the alcohol, which, of course, would stop the fermentation of yeast cells. The patient took this medicament cheerfully, and we believe it may have had something to do with her improvement.

Yeast cells are productive of para-aminobenzoic acid and for this reason we did not try sulfonamide compounds. Harford[7] failed to alter the course of the disease with massive doses of penicillin.

Since the patient's immune response was good, we tried massive doses (5 Gm. per day) of iodides. We also tried oxophenarsine hydrochloride, methylene blue and antimony compounds. None of these produced any noticeable effect. Hektoen's vaccine, immune serum and rectal instillations of ether were not tried in this case. Roentgen ray therapy was not tried.

SUMMARY

1. Yeast cells in cryptococcosis are readily recognizable in excretions. The specimen must be freshly examined and should be preferably unstained.

2. A solution of 5 per cent alcohol and dextrose administered intravenously is apparently a valuable adjunct in combating toxemia due to toxins released by budding cells.

---

[7] Harford, C. G., and others: Treatment of Staphylococcic, Pneumococcic and Other Infections with Penicillin, J. A. M. A. 127:253 (Feb. 3) 1945.

3. In case of recovery there is an immunity present, but until such immunity develops a state of hypersensitiveness exists which produces periodic attacks due to autoinfection.

4. There is a striking similarity, if not identity, in the clinical pictures of blastomycosis and cryptococcosis.

STREPTOMYCIN THERAPY IN INFECTION OF URINARY TRACT

Failure Because of Development of Resistance

AMEDEO BONDI Jr., Ph.D.
DONALD OTTENBERG, M.D.
CATHERINE C. DIETZ, M.S.
and
CHARLES L. BROWN, M.D.
Philadelphia

The development of resistance by bacteria to chemotherapeutic agents in the treatment of infectious diseases is becoming of increasing importance. With the wide usage of the sulfonamides and penicillin at present and probably of streptomycin in the near future, the problem of the development of fastness by organisms in the body during the period of treatment is a matter of great concern to the clinician. The manner in which organisms frequently become resistant to sulfonamide compounds is well recognized.[1] Development of fastness to penicillin has been observed [2] in some organisms during therapy but occurs much less frequently than fastness to sulfonamide compounds. Failure of organisms to readily develop a fastness to penicillin is probably one of the main reasons for the great effectiveness of this agent. With the newer antibiotic, streptomycin, however, the ease and speed with which organisms become resistant to it in vivo may prove to be a limiting factor in its wide usage. Although this new chemotherapeutic agent is still in its infancy, the development of resistance to it by organisms in the body during treatment has already been reported.[3]

In the following report 2 unrelated cases of infection of the urinary tract caused by Aerobacter aerogenes, a gram-negative coliform bacillus, are described, which were unsuccessfully treated with streptomycin. In both cases the ineffectiveness of streptomycin could be attributed to the development of resistance by the organisms during the course of treatment.

REPORT OF CASES

CASE 1.—F. V., a man aged 28, was admitted to the hospital with fever, chills, sweats, spastic weakness of the lower extremities, urinary retention and failing vision. The history of illness dated back to 1935. Cultures of urine repeatedly disclosed a gram-negative bacillus later identified as A. aerogenes. Blood cultures were negative. A diagnosis was made of infection of the urinary tract secondary to cord bladder due to multiple sclerosis.

The patient showed temporary improvement following a course of penicillin therapy (160,000 units a day for six days), but a low grade fever persisted and cultures of urine continued to be positive for A. aerogenes. An indwelling catheter was left in place at all times, and the bladder was irrigated by continuous tidal drainage with acriflavine in a 1 : 3,000 solution. The culture of A. aerogenes was tested in vitro for susceptibility to streptomycin by a broth dilution technic and was inhibited by 1 microgram (1 unit) per cubic centimeter of culture medium. Therapy with this agent was started in an attempt to clear up the infection. Streptomycin (1 Gm., 1,000,000 units) was administered daily by continuous intramuscular drip and was continued for five days, during which the total dosage was 5 Gm. All other forms of therapy were discontinued during the course of treatment with streptomycin. The patient failed to experience any discomfort from the injections and at no time did any significant local reaction occur. Clinical improvement was not noted at any time during the administration of streptomycin; in fact, in general the clinical condition of the patient was poorer on completion of therapy with this agent.

Cultures of Urine and Susceptibility to Streptomycin

Time in Relation to Treatment	Isolation of A. Aerogenes	Susceptibility * to Streptomycin † Micrograms/Cc.
Before treatment	Many	1.0
After treatment started ‡		
6 hours after	Few	2.0
12 hours after	None	
18 hours after	None	
24 hours after	Moderate number	>1,000.0
2 days after	Many	>1,000.0
After treatment stopped		
1 day after	Many	>1,000.0
6 months after	Many	>1,000.0

* Case 1.
† Smallest concentration inhibiting growth.
‡ 1.0 Gm. per day for five days.

Cultures were done on six-hour specimens of urine during the first day of treatment and then daily on twenty-four hour specimens. Only the second and third six-hour specimens collected during the first day of treatment were sterile. All specimens subsequently collected contained A. aerogenes (see the accompanying table). Isolations of the organism made during and after treatment were saved and later tested for susceptibility to streptomycin. All isolations obtained twenty-four hours after therapy was instituted were resistant to 1,000 micrograms of streptomycin. Blood levels of the agent varied between 7 and 10 micrograms per cubic centimeter. Levels in the urine varied between 280 and 2,000 micrograms per cubic centimeter.

The patient experienced two subsequent bouts of spiking fever with chills. Two further courses of penicillin therapy were administered, during which tidal drainage with acriflavine was continued. Subsequent to ten days of normal temperature, the patient was discharged from the hospital about three months after admission. Improvement in the neurologic condition was not observed during hospitalization. A specimen of urine collected six months after discharge still showed A. aerogenes on culture.

CASE 2.—J. M., a man aged 55, had stones in the right kidney and recurring pyelitis of several years' duration. Surgical intervention was recommended but was not done. Two months before his death, the patient had lobar pneumonia, which responded successfully to penicillin therapy. On recovery, however, pyelitis recurred, and the patient became toxic, with a temperature of 103 F., chills, sweats and hiccups; the leuko-

cytes numbered 25,000. Blood cultures were negative but cultures of urine contained enterococci and many A. aerogenes.

The culture of A. aerogenes which had been isolated was tested for susceptibility to streptomycin, and growth was inhibited by 0.5 microgram (0.5 unit) per cubic centimeter of culture medium. Streptomycin therapy was started on the ninth day after the recurrence of pyelitis. Two grams of the drug (2,000,000 units) was administered the first day by continuous intramuscular drip and 1 Gm. per day thereafter for fourteen days, making a total dosage of 15 Gm. Some general improvement in the patient was noted, but fever persisted and the temperature never returned to normal. Streptomycin levels were not computed on blood or urine. Cultures of the urine one week after streptomycin therapy was discontinued contained many A. aerogenes. Growth of the organisms isolated at this time was not inhibited by 1,000 micrograms per cubic centimeter of broth. The patient died of sepsis ten days after a nephrectomy was performed.

COMMENT

It is apparent that the failure of streptomycin to control the infection of the urinary tract in the 2 cases reported herein was due to the development of resistance to this agent by the strains of A. aerogenes causing the infections. In case 1 the development of resistance to streptomycin was rapid and occurred during the first twenty-four hours of treatment. Because the patient in case 2 was treated at some distance from the laboratory, cultures were not made during the period of treatment; hence, unfortunately, the speed with which the organisms became resistant was not determined. There is little doubt that the resistant strains isolated in both cases were variants of the original susceptible cultures. The resistant variant in each case was identical with the parent strain morphologically, culturally and biochemically.

In a study of the development of resistance to penicillin by staphylococci, Demerec[4] concluded that development of resistance to this agent by staphylococci is the result of natural selection. Klein and Kimmelman[5] more recently came to the same conclusion concerning the development of the streptomycin resistance of shigella. According to the concept of these two workers, the resistant strains of A. aerogenes which were isolated in the cases reported above were present in the parent culture of each strain. Because they were present in such few numbers, however, they were not detected by conventional methods of susceptibility testing wherein small inoculums are tested. When treatment was instituted, the susceptible cells were immediately eliminated, leaving only the few resistant forms which multiplied rapidly until the entire population consisted solely of resistant cells. We are in accord with this reasoning in view of the rapidity with which resistance developed, a process which is more consistent with that of natural selection than with that of acquired resistance.

Proof that resistant cells were present in one of the original susceptible cultures was obtained by testing the susceptibility of a large population of the culture. A total of 5 cc. of broth culture of each strain of A. aerogenes was plated in a series of agar plates containing 500 micrograms of streptomycin per cubic centimeter of agar. Not a single colony developed on the plates inoculated with strain J. M. (case 2). On the plates inoculated with strain F. V. (case 1), however, two colonies developed which on subsequent testing were not inhibited by 1,000 micrograms of the drug. It appears that of the approximately 5 billion cells of this strain tested there were two resistant variants. It is obvious that if a smaller population had been tested these resistant variants would not have been detected. No doubt strain J. M. likewise has similar resistant variants, but still larger populations must be tested before they are detected.

It is significant that the resistant variants which were isolated remained permanently resistant. An isolation of A. aerogenes from patient F. V. (case 1) made six months after streptomycin therapy was discontinued was still resistant. Furthermore, all resistant strains stored in the laboratory on extract agar slants still retained their resistance nine months after isolation.

Streptomycin has not had sufficient clinical trial as yet to justify conclusions in regard to its future chemotherapeutic value. It appears at present, however, that it will be of value in the treatment of tuberculosis[6] and certain infections due to gram-negative bacilli.[7] It is evident, nevertheless, that the rapid development of resistance to this agent by organisms in the body under treatment is a serious problem which the therapeutist must bear in mind. It may become necessary for the laboratory to devise susceptibility tests of such a nature that the probability of an organism developing resistance will be predictable. It should not be assumed that all strains of A. aerogenes or other susceptible organisms will become resistant to streptomycin as readily as did those in the 2 cases reported. Doubtless bacteria differ in their tendency to give rise to naturally resistant variants as shown recently by Knop.[8] It is interesting to note that by transferring the two parent strains of A. aerogenes each daily in broth which contained increasing concentrations of streptomycin relatively few passages were required before the two became extremely resistant.

Until an answer is found to this problem it appears that large dosages of this agent should be used. It is conceivable in the 2 cases reported that if the entire dosage had been given in the course of one or two days the response might have been more favorable. Such intensive therapy would have tended to eliminate the few resistant variants as well as the susceptible forms. The answer to this problem may eventually be the therapeutic use of some other agent, such as penicillin or a sulfonamide compound, along with streptomycin. Combined therapy may prevent the appearance of such resistant variants to either agent.[9]

SUMMARY

In 2 cases of infection of the urinary tract due to Aerobacter aerogenes streptomycin therapy was unsuccessful. The ineffectiveness of this agent was due to the development of streptomycin-resistant variants of the two strains of A. aerogenes causing the infections. The resistant variants in both cases were over a thousand times more resistant than their susceptible parent cultures.

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association
and Hygeia, the Health Magazine
Chicago

CHAPTER 1. *The Organization Is Conceived*

(NOTE: *Following is the first chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of THE JOURNAL. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in THE JOURNAL. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—ED.)

The first meeting of the American Medical Association was in May 1847 in the city of Philadelphia. The assemblage did not gather by any common impulse arising suddenly in the minds of a great number of men. The birth of the Association followed travail of many months; the pains, the jealousies and the love associated with its conception forecast the great career to be achieved by this extraordinary progeny.

A medical society was formed in New York in 1749, almost a hundred years previously. The first medical book to be published on the North American continent had been printed by the Spaniards in Mexico in 1570 and they had founded the first medical school in 1578. The only medical publication of the New England colonies in the seventeenth century was Thatcher's "Brief Rule," printed in Boston in 1677. John Shaw Billings in his notable "A Century of American Medicine" says there were at the commencement of the Revolutionary War but one medical book by an American author, three reprints and twenty pamphlets.

Before 1800 there were five good medical schools—those of the University of Pennsylvania (1765), Kings College (1767), New York, which became in 1792 the Medical Faculty of Columbia College, Harvard University (1782), the College of Philadelphia (1790) and the Medical School of Dartmouth College (1798). Small medical societies had been [illegible] in Boston in 1735 and others in New [illegible] and New Haven County. State medical societies existed in New Jersey, Massachusetts, South Carolina, Delaware, New Hampshire, Connecticut and Maryland. The medical periodicals of the country were few in number and of small circulation, the first being the *Medical Repository* of New York, founded in 1797.

With the nineteenth century medicine began to make more progress through the development of interesting devices and new theoretical concepts. Advances made in physics and chemistry were reflected, as they are today, in medicine, but the modern scientific movement did not attain full proportions until well after the middle of the century. No doubt the discovery of anesthesia in 1846 was the most important single contribution to the advancement of medical science in those first fifty years of the nineteenth century. True, the period saw the introduction of vaccination against smallpox, the discovery of the stethoscope by Laënnec, the publication of Percival's "Code of Medical Ethics," the first ovariotomy, performed by Ephraim McDowell, the publication of the first United States Pharmacopeia (1820) and such amazing clinical contributions as Bell's description of the functions of the spinal nerve roots, Parkinson's description of paralysis agitans, Hodgkin's description of lymphadenoma, Beaumont's classic experiments on digestion, Basedow's description of toxic diffuse goiter and Oliver Wendell Holmes's essay on the contagiousness of puerperal fever. Rokitansky and Virchow had begun the fundamental studies in pathology which were to be the basis of a modern science of medicine in contrast to a century of medical art. Claude Bernard had already written a significant essay on the digestive function of the pancreas.

Then came 1847. In his "History of Medicine" Fielding H. Garrison lists as the most important accomplishments of that year Helmholtz's treatise on "Conservation of Energy," the introduction by Sir James Simpson of chloroform anesthesia in obstetrics, the Semmelweis discovery of the cause of puerperal fever, the invention by Carl Ludwig of the kymograph and the founding of the Royal Academy of Sciences of Vienna and of the American Medical Association in Philadelphia.

What better source could we ask for the history of the American Medical Association from its organization up to January 1855 than Dr. Nathan Smith Davis, who, more than any other man, may be credited with being the founder of the American Medical Association? He records the incidents in his book published in 1855 in Philadelphia. At that time he said:

> Of all the voluntary social organizations in our country, none are at this time in a position to exert a wider or more permanent influence over the temporal interests of our country than the American Medical Association. This assertion may startle the mind of the professional reader and call forth a smile of incredulity, nay of contempt, from the nonprofessional; but let both patiently follow me to the end and then judge. I am aware that the details on which I am about to enter may appear to some unimportant, to others tedious and, to all of the present generation, wanting in novelty and interest; but they will appear far otherwise to those who shall come after us and live when time shall have thrown his dimming veil over all the doings of our day.

During the fifteen years between 1830 and 1845 the number of medical colleges in the United States more than doubled. There was active rivalry and competition without restraint. Because of the commercial character of these medical schools, the promoters sought by shortening of the curriculum and by the establishment of easy terms of graduation to induce great numbers of students to enter and to pay the fees. Sixteen weeks was generally adopted as the length of the college term; in some schools, it was reduced to thirteen. In New England attempts had been made to improve on this wholly inadequate curriculum. In 1835, the Faculty of the Medical College of Georgia proposed that a convention be called of delegates from all the medical colleges in the United States with a view to standardizing upward. Some of the more influential schools in the Atlantic cities, as might have been anticipated, opposed this effort. But a cry arose again in the Medical Society of the State of New York at its annual meeting in February 1839. At that time a resolution declaring that the business of teaching should be separated as far as possible from the privilege of granting diplomas was adopted by a large majority.

Following the adoption of this resolution, Dr. John McCall of Utica offered a preamble and a resolution urging a national medical convention to be held in 1840 in Philadelphia with delegates from each state medical society and each medical school in the United States. The resolution was adopted, and all the necessary steps to make it effective were taken. Then neither the societies nor the schools of other states responded to the invitation. The evil persisted, and the tension accumulated during the years that followed. In 1844 a series of resolutions were offered by Dr. Alexander Thompson of Cayuga County and N. S. Davis of Broome County attacking the abuse of the procedure by which college faculties both taught and licensed medical students and attacking as well the brief course of education leading to the receipt of a diploma. In 1845 the discussions in the state society continued; but the pattern of thinking seems to have been as stereotyped as it is now whenever improved standards are urged in any branch of education. Those who wished to set up a high standard in New York were told that students would abandon the schools of New York for those of other states where the requirements were less. The statement was made again and again that the requirements in New York were certainly as high as those of other states. At the close of the debate in 1845 Dr. Nathan Smith Davis, urged by Dr. Alden March of Albany, introduced the resolution which follows and which may be considered the first step toward the formation of the American Medical Association as we know it now:

> WHEREAS, It is believed that a national convention would be conducive to the elevation of the standard of medical education in the United States; and
>
> WHEREAS, There is no mode of accomplishing so desirable an object without concert of action on the part of the medical colleges, societies and institutions of all the states; therefore be it
>
> *Resolved,* That the New York State Medical Society earnestly recommends a national convention of delegates from medical societies and colleges in the whole Union to convene in the city of New York on the first Tuesday in May in the year 1846 for the purpose of adopting some concerted action on the subject set forth in the foregoing preamble.
>
> *Resolved,* That a committee of three be appointed to carry the foregoing resolution into effect.

The introduction of this resolution was followed by a discussion in which the older members of the society told how similar movements had failed in the past. Others said that the whole project was impracticable if not positively utopian. But Nathan Smith Davis persisted and urged those who agreed with him to persevere until they achieved success. The resolution was adopted; a committee consisting of Drs. Nathan Smith Davis of Binghamton, James McNaughton of Albany and Peter Van Buren, secretary of the state society, were named to make the resolution effective.

To what, then, can be ascribed the success of this resolution compared with the repeated failures of previous attempts to found a national medical society? The persistence and courage and initiative of Dr. N. S. Davis were the essential factors. Dr. Nathan Smith Davis soon after his return to Binghamton sent a copy of the preamble and resolutions to every college and medical society known to exist in the United States and to many prominent physicians in sections of the country in which such societies had not yet been formed. The proposal met with favor from societies, colleges and individuals by whom it was received except the colleges located in Philadelphia and in Boston. These schools respectfully declined to take any part in the proposed convention. The medical periodicals of the country, however, commended the holding of such a convention. Dr. Davis continued indefatigably to urge support of his project.

The New York State Medical Society in February 1846 appointed sixteen delegates to attend and accepted the invitation of the Faculty of the New York University to hold the convention in their building in May of that year. With an organizational genius equal to the best modern technics, Dr. N. S. Davis sent more communications to the medical periodicals of the country during 1845. He was aided by similar communications from Dr. Luther Ticknor, then president of the Medical Society of the State of Connecticut. Whereas Dr. Davis emphasized particularly the improvement of medical education, including higher standards of preliminary education, the quality of teaching, the qualifications required for a diploma and continuous stimulus of the medical profession, Dr. Ticknor urged quality in medical practice and graduate education and deprecated particularly the rivalry among the medical institutions and leading medical men as to who should furnish "not the most valuable and best wrought article, but who shall furnish the greatest quantity." So strong indeed were the language and the assertions of Dr. N. S. Davis that they naturally stimulated some opposition.

Professor Martyn Paine of the medical department of New York University delivered an address called "A Defense of the Medical Profession of the United States," published it and circulated it widely throughout the country. In this address he attacked the state medical society, accusing it of playing politics in its desire to extend the curriculum and said:

> There is an aristocratic feature in this movement of the worst omen, however the spirit, by which it is prompted, may belong to the agrarian policy. It is oppression toward the poor for the sake of crippling the medical colleges.

This address had the strange effect of causing the Philadelphia physicians to withdraw their previous rejection of the invitation to New York on the grounds that "the very singular address of Professor Paine" convinced them that the "convention was not designed particularly to benefit the medical schools in the city of New York." As a result, the society was convened in Philadelphia and twelve eminent physicians were appointed to attend the meeting in New York. In his book Dr. N. S. Davis philosophizes on this incident as exemplifying the necessity for frequent contacts between leaders in order to overcome distrust and bring about mutual respect. He says:

> It would be difficult to illustrate more strikingly that sleepless jealousy which pervaded more or less all our medical schools, springing into existence in rapid succession, as they had done; or the necessity of some general organization, by which the representatives of all should be brought into personal contact and intercourse, until mutual distrust should give place to mutual respect and a common object.

THE ORGANIZATIONAL MEETING

On Tuesday, May 5, 1846 the delegates and members of the medical profession from different parts of the United States assembled in the hall of the Medical Department of the New York University. Dr. Edward Delafield of New York was in the chair. Dr. William P. Buel of New York was appointed secretary. On motion a committee of one from each state represented in the convention was appointed to nominate officers for the convention. This committee unanimously agreed to propose for president Dr. Jonathan Knight of New Haven, for vice presidents Dr. John Bell of Philadelphia and Dr. Edward Delafield of New York City, and for secretaries Dr. Richard D. Arnold of Savannah, Ga., and Dr. Alfred Stillé of Philadelphia.

The Committee on Credentials reported that 119 delegates had sent credentials and that 80 of these were present at the opening of the convention. They represented medical societies and colleges from sixteen different states. No sooner had the officers been elected and conducted to their respective places than there occurred one of the most extraordinary political moves that has ever marked a medical assemblage anywhere in our country, which, incidentally, is widely known for the exciting activities of its democratic assemblages. Dr. Gunning S. Bedford, a colleague of the previously mentioned Professor Martyn Paine, arose and, after some general remarks as to the benefits of a general convention of medical men, introduced a resolution to the effect that the assemblage had failed in representation from half the United States and from a majority of the medical colleges and that therefore "this convention adjourn *sine die*." The proposition was immediately seconded by one of his associates and naturally took the convention by surprise. There were two minutes of silence. The question was called for and a vote being taken gave 2 voting "Yes," namely Dr. Gunning S. Bedford and his colleague Dr. G. S. Pattison, and 74 "No."

Since many of the members considered the resolution an insult, motions were promptly made to withdraw the convention from the hall of New York University. This was followed by explanations and apologies by Drs. Bedford and Pattison; then the proposed withdrawal was laid on the table.

A committee of nine was appointed—headed by Dr. N. S. Davis—to bring the subject of medical education before the convention in the form of distinct proposals suitable for discussion and action and to report at the next meeting. On the following day this committee presented to the convention the following four proposals:

> First. That it is expedient for the medical profession of the United States to institute a National Medical Association.
>
> Secondly. That it is desirable that a uniform and elevated standard of requirements for the degree of M.D. should be adopted by all the medical schools in the United States.
>
> Thirdly. That it is desirable that young men, before being received as students of medicine, should have acquired a suitable preliminary education.
>
> Fourthly. That it is expedient that the medical profession in the United States should be governed by the same code of medical ethics.

The committee also recommended the appointment of a committee of seven "to prepare and issue an address to the different regularly organized medical societies, and chartered medical schools in the United States, setting forth the objects of the National Medical Association, and inviting them to send delegates to the Convention to be held in Philadelphia in May 1847."

The proposals were adopted by the convention and the committees were appointed.

At this same meeting Dr. Davis tried to introduce—and received support for—a resolution to the effect that the union of the business of teaching and licensing in the same hands is wrong in principle and liable to abuse in practice. The resolution was opposed by Dr. Isaac Hays and by other members of the committee and finally was presented to the convention. Here it was fully discussed, and motions were made to lay it on the table or to refer it to various committees, but the spirited defense by Dr. N. S. Davis resulted finally in reference of the resolution to a special committee of seven, with instructions to report it at the meeting to be held in Philadelphia in May 1847.

This assemblage of physicians did not lose the opportunity to make progress toward greater efficiency in the science of medicine. On motion of Dr. John H. Griscom, committees were appointed to report on the most efficient measures for effecting a registration of births, marriages and deaths and toward the establishment of a nomenclature of diseases adapted to the United States.

Dr. N. S. Davis, looking over this epoch-making meeting in retrospect, expresses his surprise at the disparity of representation from states located equally distant from the place of meeting. New Jersey, for instance, had only two delegates, Maryland only one and Georgia only one. Indiana and Illinois had only one delegate each, so that more than half of the entire number present represented the state of New York. Eleven medical colleges were represented, which were only one third of the whole number in the United States. Again in retrospect, Nathan Smith Davis was disappointed by the absence of those to whom the medical profession had been accustomed to look as leaders in all important professional matters. He calls attention to the absence of such men as Warren, Mussey, Stevens, Chapman, Drake. Later most of these were to become quite active in the work of the medical association and some of them were elected to the presidency.

Clinical Notes, Suggestions and New Instruments

ACUTE INFECTIOUS LYMPHOCYTOSIS IN AN ADULT

Review of Literature and Report of Case

ANTON S. YUSKIS, M.D.
San Diego, Calif.

Acute infectious lymphocytosis is a clinical entity characterized by a benign relative and absolute increase in the number of mature lymphocytes. This condition was first described by Smith[1] in 1941. He expressed the opinion that the group of cases reported by Reyersbach and Lenert[2] and that by Wilson and Cunningham[3] were examples of this disease rather than of infectious mononucleosis, because there were no significant clinical signs or symptoms in any of these cases. Thelander and Shaw[4] also reported 2 cases that should have been classified as acute infectious lymphocytosis. Duncan[5] reported a case of infectious lymphocytosis that presented a definite symptomatology and Smith[6] recently reported 4 cases in which he considered the disease to be both infectious and contagious. Birge and Hill[7] reported a differentiation between leukemia, mononucleosis and pertussis. They stated that the only change observed in the aspirated bone marrow was a slight increase in small lymphocytes, and that immature cells appeared in the peripheral blood in acute leukemia but not in acute infectious lymphocytosis. For the diagnosis of pertussis in the absence of characteristic physical observations, bacteriologic studies should be an aid, since the lymphocytic response to infection produces fewer cells than are apparent in acute infectious lymphocytosis.

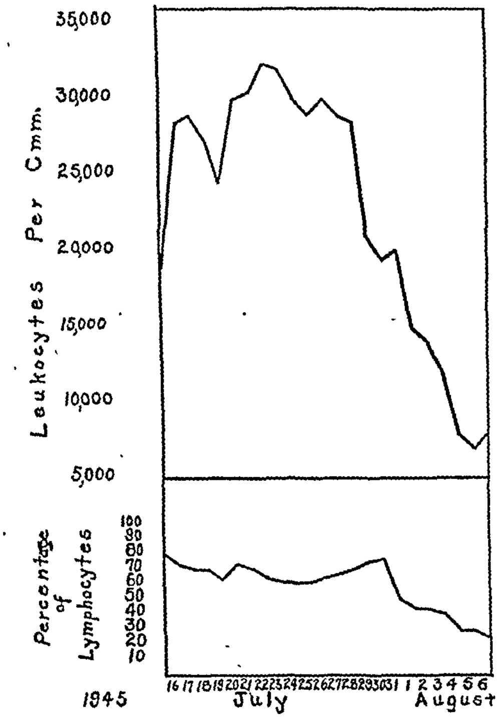

Chart 1.—Hematologic data; increase in the number of mature lymphocytes.

All the cases which were reported occurred in children under the age of 9, until Duncan[8] in 1945 reported 2 cases occurring in young adults. The purpose of this report is to present a case also which occurred in an adult.

REPORT OF CASE

History.—A man aged 29, a recruit in a Naval Training Center, reported to the dispensary on July 16, 1945 complaining of a moderately severe pain in his right side which occurred after his training on the obstacle course. He received diathermy and salicylates for the next three days with but slight improvement, and the pain had shifted to his right hip. A white cell count, a urinalysis and a roentgenogram were requested, and the laboratory reported a normal urinalysis and a white blood cell count of 19,200 with a differential count of 80 per cent mature lymphocytes, 18 per cent neutrophils and 1 per cent each of eosinophils and basophils. Because of the hematologic observations he was admitted to the dispensary for observation.

Several days before his induction into the service on July 5, 1945 the patient noted a rash that had occurred below the belt line and covered the lower part of the abdomen, both hips, thighs and legs. Otherwise, the past history was noncontributory.

Physical Examination.—On physical examination, the patient was a well developed, well nourished white man who appeared much older than his stated age of 29. The temperature, pulse rate, respiratory rate and blood pressure were normal. The rash which was still present on his hips, thighs and legs consisted of a symmetric red maculopapular eruption, grouped together in places to form irregularly shaped lesions which became confluent, especially over the tibial surfaces. Itching was absent. The head, neck, chest and abdomen were normal. The lymph glands were not enlarged, and the spleen and liver were not palpable.

Laboratory Data.—Roentgenograms of the chest, pelvis and femurs were negative. Urinalysis was normal and the heterophil agglutination tests were positive in a dilution of 1:8. The blood platelet count was normal as was the electrocardiogram. The sedimentation rate was 8 mm. (Cutler method). Repeated determinations of the erythrocyte count which averaged 4,630,000 and the hemoglobin content which averaged 14.8 Gm. were well within normal limits. The proportion of large mononuclear cells never exceeded 3 per cent. The bleeding and clotting times of the blood were normal. The only significant hematologic observation was the increase in the number of mature lymphocytes as shown in chart 1.

Course.—While in the dispensary the patient did not have any complaints. The rash disappeared two days after admission, and he was returned to duty on Aug. 6, 1945. Eleven days later on Aug. 17, 1945 he was readmitted to the dispensary because of a mild infection of the upper part of the respiratory tract—headache, sore throat, cough and an elevation of temperature to 101 F. without other abnormal observations. His condition improved immediately, and he was returned to duty about one week later. The hematologic data during this time and at subsequent dates are shown in chart 2.

The patient finished his "boot training" and after he returned from his "boot leave" a complete physical and laboratory examination on Oct. 17, 1945 failed to reveal any abnormalities.

COMMENT

Smith[6] recently summarized the data for the establishment of acute lymphocytosis as a specific entity and differentiated it from infectious mononucleosis, acute lymphatic leukemia and miscellaneous infections associated with a lymphocytosis.

Most of the reported cases have been in children until Duncan[8] reported 2 cases occurring in young adults. In this same report, Duncan had a case in which there was a morbilliform rash lasting for four days during the first week of the disease. In this case the rash which was present lasted about twenty-one days. Because of this rash, a diagnosis of infectious mononucleosis was seriously considered, but a careful clinical, hematologic and serologic study failed to substantiate this diagnosis and corroborated the factors of differentiation which were stressed by Smith.[6]

In most of the cases, including this case, reported in the literature, the disease is uncomplicated and has a uniformly favorable outcome. The clinical manifestations are usually mild or absent, or if severe they are of short duration. In none of the cases was there lymphadenopathy or splenomegaly, and in all instances the heterophil reaction was negative. The maximum white cell count was 49,200 with 88 per cent lymphocytes. A characteristic feature in all cases, including this one, is either

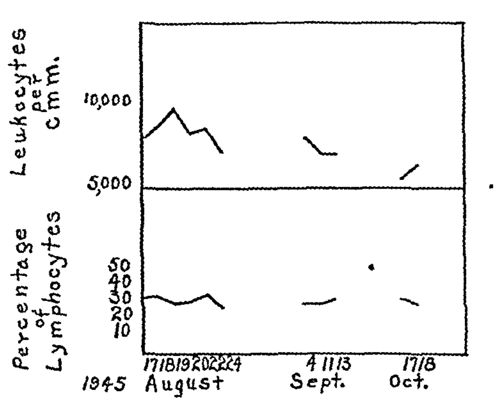

Chart 2.—Hematologic data during and subsequent to second hospitalization.

[8] Duncan, P. A.: Acute Infectious Lymphocytosis in Young Adults, New England J. Med. 233: 177-179 (Aug. 9) 1945.

the total absence of symptoms and physical signs or the short duration of mild symptoms and signs with the hyperleukocytosis continuing for a period of approximately three to five weeks. In some cases pain is present and may represent a striking symptom, and if it is, abdominal surgical intervention may result. In this case the pain was moderately severe but was never considered a basis for surgical intervention.

Smith[6] in his latest report stated that the disease is both infectious and contagious and has a possible incubation period of twelve to twenty-one days. In this case several friends of the patient from his company were questioned and examined but did not reveal any abnormality, particularly from the hematologic examination.

SUMMARY

1. A case of acute infectious lymphocytosis has occurred in a young adult.
2. A rash which accompanied the infection is described as similar to that previously reported for the first time in conjunction with this disease.
3. A review of the present literature on acute infectious lymphocytosis indicates that the disease is infrequently encountered.

3118 El Cajon Boulevard.

PROGERIA WITH NANISM AND CONGENITAL CATARACTS IN A FIVE YEAR OLD CHILD

ROBERT C. MOEHLIG, M.D.
Detroit

Progeria with nanism is infrequently encountered in practice, and its association with congenital cataract is most unusual.

The following is a case report of this disease associated with congenital cataracts.

REPORT OF CASE

W. H., a boy aged 5, was seen March 27, 1944, at the request of Dr. E. Alford of Belleville, Mich.

He was born two months prematurely, on July 27, 1938. Through the kindness of Dr. Otto Grob, I was furnished with the important points taken from his own records and those of the Children's Hospital of Michigan.

The weight at birth was 3 pounds 2 ounces (1,366 Gm.) and the length was 44 cm. The circumference of the head was 25 cm. The nose was pointed. The infant was discharged on September 15 and readmitted October 24 because of diarrhea and difficulty with feeding. He was given protein, calcium lactate, percomorph and ammonium citrate and green iron.

Comparison of Normal Measurements With Those of Patient

	Measurements in Cm.	
	Normal	Patient
Head	52.0	47.0
Chest	48 0	46.3
Waist	52.0	44.0
Span	105.0	94.0
Upper	59.0	50.8
Lower	49.5	45.7
Height	109.0	96.5
Weight	18.0 Kg.	12.0 Kg.

Dr. Davies, the ophthalmologist, who saw the infant in consultation summarized the observations as follows: The external eyes were negative except for a bluish tint to the scleras and shallow anterior chambers. The tactile tension was normal. Both lenses showed decided cataractous changes through undilated pupils. Only a faint fundus reflex was seen. The diagnosis was bilateral congenital cataracts.

The roentgenologic report disclosed that the long bones were relatively long and thin with a rather delicate cortex, and except for the humeri the cortex was not reduced enough for an absolute diagnosis of fragilitas ossium. The calcification of the cranial bones was delicate. The chest was normal.

On October 30, Dr. O. Grob made note of bilateral congenital cataracts. A week earlier, on Oct. 24, 1938, the hemoglobin level had been 9.3 Gm. per hundred cubic centimeters; erythrocytes 3,060,000, and leukocytes 6,100, of which 84 per cent were lymphocytes. The Kline test was negative.

When Dr. Grob saw the patient again on Oct. 30, 1939, he weighed 5,800 Gm. Dr. Grob made the following observations: (1) Very small; (2) congenital cataract, bilateral; (3) marked nasal obstruction; (4) low mentality? and (5) child has blue spells and holds his breath.

The teeth came in slowly when the boy was 3 years of age; when he was seen at the age of 5, they were small, undeveloped and had a well defined deposit of calcium on the crowns.

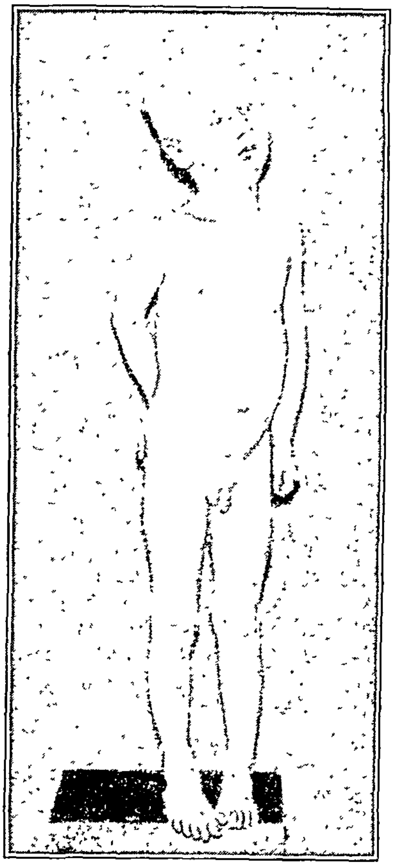

Fig. 1.—Front view of patient; typical characteristics of progeria.

He was mentally retarded, but the intelligence quotient was not determined. He used only one or two words at a time when speaking. He did not sit up alone until the age of 16 months. He was unusually hungry, but despite this his growth and weight were retarded. He walked soon after learning to sit up.

At the age of 3, he began to play the piano without having had lessons and played such numbers as Song of India and Turkey in the Straw. The mother said he could play any song after hearing it once. He was constantly drooling. He was impish and mischievous. He frequently held the flat of his right hand in front of his eyes and with a rapid motion kept the hand moving up and down.

Dr. F. Bruce Fralick of the University of Michigan Hospital reported on the patient as follows:

W. H. was first seen in the clinic on June 2, 1942. At this time, diagnoses were made of aphakia of the left eye and nystagmus, congenital cataract of the right eye and left divergent strabismus. On July 1, 1942, needling of the congenital

---

From the Department of Medicine, Harper Hospital, and Wayne University College of Medicine.

cataract was performed on the right eye. The postoperative course was uneventful and on July 15 the eye was seen to be quiet, with the cortical material dissolving satisfactorily. There was a thin secondary cataract present with one or two small posterior synechias. Fundus details were not clear at this time. He was given a prescription for plus 10.00 sphere for each eye with a plus 2.50 added for near vision. He has not been seen in the clinic since that time.

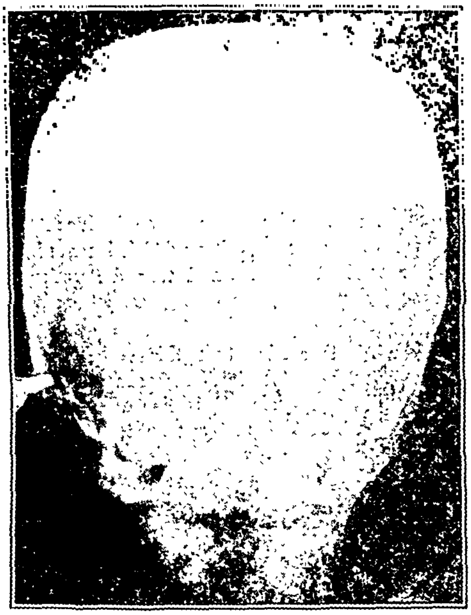

Fig. 2.—Roentgenogram of skull, anteroposterior view; incomplete closure of sagittal and lambdoidal sutures.

The past history disclosed that the patient had none of the usual childhood diseases. The family history indicated that the father was living. His height was 76 inches (193 cm.) and his weight 165 pounds (74.8 Kg.). The mother was living and her height was 64 inches (162.56 cm.) and her weight 120 pounds (54.4 Kg.) She had had a thyroidectomy for an adenoma of the thyroid. A paternal uncle was, like the father, 76 inches (193 cm.) in height. A paternal cousin of the patient also was of the same height and weighed 289 pounds (131 Kg.). There were three brothers, one of whom grew "too fast." The mother's father was 72 inches (182.88 cm.) in height.

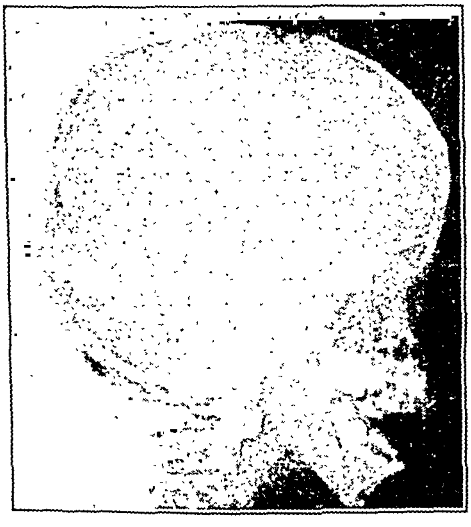

Fig. 3.—Roentgenogram of skull, lateral view.

The physical examination showed a boy who had a definitely senile appearance, typical of progeria (fig. 1). The face had the characteristics of a "newly hatched bird." The hair of the scalp was sparse and blond, with baldness of the frontal area. The veins of the temporal area were prominent. The eyebrows were poorly developed and were almost totally absent. The eye lashes were absent. The upper part of the ears protruded from the head; the lower part was flat.

The blue eyes showed a constant horizontal nystagmus which was doubtless congenital. The left eye showed aphakia. The right eye displayed a left divergent strabismus.

The nose was aquiline in appearance; the septum was deviated. The mouth was small and purselike. The boy drooled a great deal. The teeth were unusually small and carious and had a thick white deposit on them. The hard palate was of the high arched cathedral type. The tongue was normal in appearance. The tonsils were large. The cervical glands were enlarged. The thyroid was small. The chest was small and asthenic. The lung sounds were normal.

The heart was not enlarged, but a loud systolic murmur was heard at the apex. The abdomen was prominent; abnormal masses were not felt. Umbilical hernia was not present. The testicles were high up in the inguinal canal. The penis was small. Pes planus was present. The skin of the face was taut and dry, as was the skin of the body. The fingers and toes were small. The patellar reflexes were exaggerated. A questionable bilateral Babinski reflex was present. The accompanying table gives the patient's measurements.

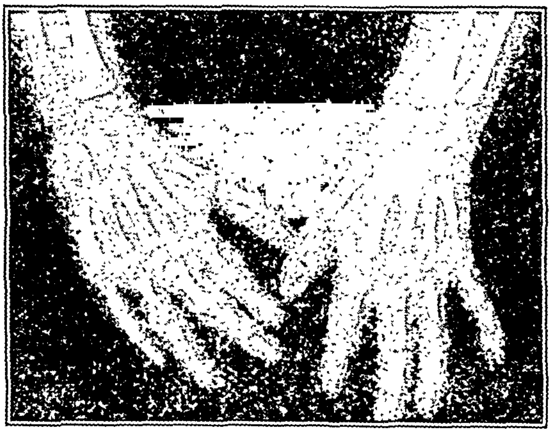

Fig. 4.—Roentgenograms of hands and wrists; osteoporosis of bones.

Roentgenograms of the skull, hands and wrists revealed the following data: The skull on examination showed that the fontanel was closed although the sutures, both sagittal and lambdoidal, were not completely fused. There was a metopic suture of the frontal bone (figs. 2 and 3).

Films of the hands and wrists revealed no material disturbance in epiphysial development, but there was definite disturbance in the bony architecture, particularly of the phalanges and metacarpals. The bones were osteoporotic (fig. 4).

The blood count was hemoglobin 78 per cent (Sahli), red blood cells 4,350,000 per cubic millimeter and leukocytes 11,450. The differential count was polymorphonuclear neutrophils 72 per cent, small lymphocytes 27 per cent and large lymphocytes 1 per cent. The results of urinalysis were normal. No blood chemistry studies were made, and the observations are therefore clinical in nature.

The patient was placed on a regimen of methyl testosterone 10 mg. per day, and on July 10 his height was 40 inches (101.6 cm.) and his weight was 30 pounds (13.6 Kg.). He was continued on this therapy, and on Jan. 6, 1945 his height was 41.4 inches (105 cm.) and his weight was 35 pounds (15.9 Kg.). He continued the testosterone therapy, and by January 6 the testicles had descended into the scrotum. According to his mother he seemed brighter and talked more but was impish and mischievous. In the office he was constantly on the move, taking objects from the examining table and turning the door knob. On November 26 his height had reached 45 inches (114.3 cm.) and his weight 38 pounds (17.2 Kg.). This represents a gain of 17.8 cm. in height and 5 Kg. in weight within a period of eight months.

COMMENT

Progeria with nanism is a rare disease. It has been termed Hutchinson-Gilford disease. Recently Thannhauser[1] described Werner's syndrome (progeria of the adult) and Rothmund's syndrome. Thannhauser's review is an extensive and comprehensive one and covers all features of these syndromes. In the differential diagnosis between diseases related to Werner's syndrome (progeria of the adult) and Rothmund's syndrome he considers progeria of children with nanism.

He lists some of the characteristics of progeria of children with nanism as follows: "Progeria of children (Hutchinson-Gilford's syndrome), also called 'nanism senile' or 'progero nanie,' is a disorder which develops from a few months to three years after birth. In the cases reported the children were normal at birth. There was no history of familial occurrence of this disorder or of the interrelationship of the ancestors. The main clinical features observed almost uniformly in all cases were as follows: All the children with progeria looked alike. The published photographs look like the pictures of twins.

"All patients were dwarfed in stature. The skull was large in comparison with the face. The frontal and parietal bones were unduly prominent. The fontanels closed early. The scalp hairs were present at birth but became grayish and scarce, and completely disappeared in the course of the disease. There was either very little or no development of the eyebrows. The eyelashes were rare or absent. The faces of these children resemble those of newly hatched birds."

In his comment Thannhauser[1] said: "There is a certain similarity in the features of 'Werner's syndrome' and 'progeria with nanism' in children. The cases exhibiting Werner's syndrome are short, almost dwarfed in stature. In progeria of children the patients are definite dwarfs. In both syndromes the extremities are short and the abdomen disproportionately large. The fingers and toes are short, and the joints of the extremities are deformed in both instances. The skin is atrophic and taut on the extremities. The panniculus adiposus of the forearm and lower legs is poorly developed as are the muscles, in both disorders. The lack of hair is more pronounced in progeria of children than it is in Werner's syndrome. Sexual retardation is present in both syndromes. Diffuse arteriosclerosis, osteoporosis and the premature senile appearance are the most impressive features present in Werner's syndrome, as well as in progeria of children. The autopsy findings in both syndromes are diffuse arteriosclerosis and no definite changes in endocrine organs. Progeria of children, however, differs from Werner's syndrome as follows: (1) There is no familial occurrence. (2) There are no pressure ulcers of the skin. (3) There are no cataracts. (4) The abnormal features develop in early childhood in progeria of children, whereas in Werner's syndrome they become evident in the second decade of life.

It is suggested that progeria of children and Werner's syndrome result from multiple germ plasm defects manifesting themselves at different ages in abiotrophic features of the genotypic kind."

In a personal communication Thannhauser stated that he did not find a case of progeria in children with cataract, in contrast to such observations in progeria of the adult. He agreed that the case herein reported is one of progeria.

Talbot and his associates[2] gave a comprehensive report of a case with metabolic studies. This case came to autopsy. The summary and conclusion were as follows: "A 7½ year old boy with typical progeria was studied. The life history and the clinical and postmortem studies failed to explain the unique appearance, the dwarfing and the loss of subcutaneous tissue characteristic of this disease.

Metabolic studies revealed that the patient ingested and assimilated a quantity of food adequate for the maintenance and growth of normal children of similar body weight. It appeared, however, that all the calories in the diet were used to meet the basal and intermediary requirements of energy metabolism, thus leaving no residue for growth or for the accumulation of subcutaneous fat. Under the influence of testosterone therapy the patient gained a greater weight of musculature, according to the data on nitrogen and potassium balance, than he gained in total body weight. This was interpreted to mean that he had burned a significant amount of stored body fat to pay for the caloric deficit incurred by building muscle. The final studies showed that the patient could be made to gain by reducing the energy output with the aid of thiouracil.

It is concluded, therefore, that this patient with progeria was suffering from a metabolic disturbance which was characterized chiefly by an excessive utilization of calories for energy metabolism and which did not appear to be due to hyperthyroidism as it is ordinarily encountered in children. As a consequence of the hypermetabolism, even when the patient was assimilating a good diet, few if any calories were available for growth. It may be profitable to search for a similar disturbance in other types of patients who fail to gain or grow."

Thannhauser said that: "Werner, as well as Rothmund, suggested that we are dealing with a disorder of the ectodermal layer, since both skin and lens are derived from the ectoderm. Such a theory is not substantiated by the multiplicity of symptoms, involving blood vessels, subcutaneous fat tissue, muscles and endocrine glands; especially not since we know the symptom complex of a heredofamilial disorder involving only the ectodermal layer—'ectodermal dysplasia of the anhydrotic and hydrotic type' which is entirely different from the syndrome under discussion." Thannhauser is inclined to the view that the occurrence of defects of the entire germinal plasm, recessive in heredity, was the most plausible explanation of the pathogenesis of Werner's as well as Rothmund's syndrome.

It is of some interest that in mongolism, as well as in progeria of the adult, cataract is not uncommon. Likewise, mongols are fond of music, as was the child in the case of progeria here reported. This fondness for music in persons whose mental caliber is low to the point of idiocy is in contrast to the large number of intellectual musical geniuses. As is well known, there are many child prodigies in the musical field. Music has a soothing influence on the agitated mental states of psychotics. Such comparative studies must be of intense interest to psychiatrists. The appeal of music to the emotions is, of course, an almost universally shared reflex.

SUMMARY

A case of progeria with nanism and congenital cataracts was observed in a 5 year old boy. Progeria with nanism and cataracts is not unusual in Werner's syndrome of the adult, but the association of cataracts is a rare condition as a congenital defect. The child was born prematurely and at birth weighed 1,366 Gm. His growth was retarded. The cataract of the left eye disappeared spontaneously when he reached the age of 3 years. He was mentally retarded but even at the age of 3 had an unusual talent for music. Methyl testosterone 10 mg. was given in daily doses which resulted in an increase of 17.8 cm. in height and 5 Kg. in weight within a period of eight months.

Council on Foods and Nutrition

The Council on Foods and Nutrition has authorized publication of the following report.

James R. Wilson, M.D., *Secretary.*

STANDARDS ESTABLISHED FOR ENRICHED MACARONI

Nineteen states and two territories have enacted legislation requiring enrichment of white flour, bread and rolls. Enrichment of flour elsewhere in the country is by the voluntary action of the millers; enrichment of commercial white bread and rolls at present is required by War Food Order No. 1. That this standardized addition of thiamine, riboflavin, niacin and iron to these products has done much to improve the quality of the American diet is indicated by analyses of foods consumed in 1943 and 1944. Consumption studies show that without enrichment of its bread and flour the per caput diet in the United States would provide considerably less than the recommended allowances of the nutrients added to bread and flour in their enrichment.

The Council on Foods and Nutrition of the American Medical Association has consistently opposed indiscriminate addition of vitamins and minerals to foods. It has, however, encouraged such enrichment in certain instances, notably in the case of cereal grain products which contribute importantly to the diets of significant groups of the population.[1] Macaroni clearly falls within the category for which enrichment is endorsed. While the average per caput consumption of macaroni and related substances, spaghetti, vermicelli and noodles, is small, some parts of the population consume these foods in quantities much larger than the average. Also many of these people are in lower income brackets and therefore not infrequently obtain the cheaper brands of flour which are unenriched. Thus the case for enrichment of macaroni and noodle products is reasonably strong, and on the basis of such evidence presented at public hearings the administrator of the Federal Security Agency now has established standards of identity for enriched macaroni, enriched spaghetti, enriched vermicelli and enriched noodles.[2]

The "order" on enrichment of macaroni and related products became effective Oct. 7, 1946. The "order" does not require enrichment of these foods but gives the macaroni manufacturer permission to enrich his major products; following the example of the milling and baking industries, he is expected voluntarily to use the opportunity to improve the nutritional quality of his products. The approximate cost of the vitamins and minerals which must be added in the preparation of macaroni products is about 12 cents per hundred pounds based on wholesale prices existing at the time of the public hearings. The cost is higher than enrichment costs for bread and flour for the reason that somewhat stronger enrichment is required to compensate for cooking losses; even so, the cost is very small.

Recently reported is a study of the nutritive value of the per caput food supply for the United States.[3] It covers the years 1909 to 1945 and reveals a great improvement in the nutritional quality of the diet in the recent war years. Largely responsible was increased consumption of milk, leafy green and yellow vegetables and citrus fruits. However, milk, vegetables and fruits contribute rather unimportantly to supplies of iron, thiamine and niacin, and the increased supply of them was credited in large part to enrichment of white bread and flour. The supply of other sources of iron, thiamine and niacin, such as meats, nuts and legumes, did not increase to any great extent.

The contributions to the better average diet attributed to enrichment of flour and bread were calculated by the government statisticians on the assumption that enrichment in 1944-1945 affected only 65 per cent of the total supply of flour and commercial bread and rolls. Estimates made by others are higher than this, but in any case a gap persists between the total amount of wheat endosperm, namely white flour and granular equivalents, which at present is consumed as food and that part of the total which reaches the consumer in products enriched by the manufacturer. A sizable amount of all wheat endosperm prepared for human consumption, not less than 5 per cent, goes into macaroni and related products, and enrichment of these products will represent another step in the direction of securing nutritional improvement for all foods derived from wheat endosperm.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

BACTERIAL VACCINE MADE FROM H. PERTUSSIS COMBINED WITH BACTERIAL ANTIGEN MADE FROM H. PERTUSSIS.—Pertussis Endotoxoid-Vaccine.—A suspension of Hemophilus pertussis, phase I organisms, in a solution of H. pertussis endotoxoid. The bacterial suspension is prepared after the technic of Kendrick and Eldering, and the endotoxoid by the Strean method.

Actions and Uses.—Pertussis endotoxoid-vaccine is recommended for the active immunization of individuals who are susceptible to pertussis. It is not intended for treatment of the disease or for the production of immunity once exposure has taken place.

Dosage.—For children 4 years of age and older a total amount of 6 cc. should be administered subcutaneously in four doses twelve to fourteen days apart as follows: 1 cc., 1.5 cc., 1.5 cc., 2 cc. For children under 4 years of age the dose may be reduced for the initial injection; a satisfactory dosage schedule consists of five injections, also at twelve to fourteen day intervals, as follows: 0.5 cc., 1 cc., 1 cc., 1.5 cc., 1.5 cc. After completion of the preliminary course it is customary to give a fortifying dose of 2 cc. (one injection) each year up to 5 years of age. When it is inconvenient to have the patient return for injections more than three times, three injections can be given at twelve to fourteen day intervals, as follows: 1 cc., 2 cc., 2 cc. Dosage intervals of one month may be preferred in cases in which the additional length of time required for vaccination is not objectionable.

Ayerst, McKenna & Harrison, Ltd., New York

Pertussis Endotoxoid-Vaccine: 6 cc. vial (one immunization) and 24 cc. vial (four immunizations). Each cubic centimeter contains approximately 15,000 million killed H. pertussis (phase I) suspended in formalin-detoxified antigen (endotoxoid). Preserved with Merthiolate 1:20,000.

U. S. patent 2,371,002.

PENICILLIN OINTMENT (See The Journal, Nov. 2, 1946, p. 515).

The following dosage forms have been accepted:

E. R. Squibb & Sons, Inc., New York

Penicillin Calcium Ophthalmic Ointment: 3.6 Gm. tubes. Each gram contains 1,000 units of penicillin calcium in a base consisting of petrolatum 40 per cent, beeswax 4 per cent, anhydrous lanolin 10 per cent and peanut oil approximately 46 per cent.

Schenley Laboratories, Inc., New York

Penicillin Calcium Ointment: 28.35 Gm. tubes. Each gram contains 1,000 units of penicillin calcium in a base consisting of white petrolatum, U. S. P., 78 per cent, mineral oil 3.5 per cent, beeswax 3.5 per cent and anhydrous lanolin, U. S. P., 15 per cent.

THEOPHYLLINE ETHYLENEDIAMINE (See New and Nonofficial Remedies, 1946, p. 395).

The following additional dosage form has been accepted:

H. E. Dubin Laboratories, Inc., New York

Aminophyllin Rectal Suppositories: 0.5 Gm.

SATURDAY, NOVEMBER 16, 1946

THE CENTENNIAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION

The Centennial Session of the American Medical Association will convene in Atlantic City, June 9-13, 1947. By action of the House of Delegates the Board of Trustees established a special Committee on Centennial Celebration. That committee has cooperated fully with the Council on Scientific Assembly and with the Board of Trustees in arrangements for celebration of the centennial with a view to making it one of the greatest and most interesting medical assemblages ever convened.

Each of the scientific sections of the American Medical Association has been authorized to secure a distinguished speaker from abroad and to include also in its program a review of medical progress in the specialty concerned for the hundred year period. Dr. Edward L. Bortz, chairman of the Council on Scientific Assembly, has taken the responsibility with his Council for the development of a program of General Scientific Meetings, to be held on Monday afternoon and Tuesday morning and afternoon of the annual session. A distinguished guest from abroad has been secured for each of these. Each of the General Scientific Meetings will provide for the presentation of three papers constituting reviews of the advancement in the fields discussed, followed by panel discussions on such subjects as the modern management of heart disease, emergency surgery and antibiotics in therapy. The individual manuscripts for presentation will include such subjects as the use of radioactive products in medicine, advancement in the field of psychosomatic medicine, the use of antihistamine preparations, uterine bleeding, the modern management of cancer, nephrosis and nephritis, and the care of the skin of the elderly. The Journal will announce shortly the details of this program, with the names of the speakers and the subjects to be discussed.

The secretaries of the scientific sections have reported extraordinary interest in the program for the Atlantic City session, with more applications for places on the program than have been received since before the war. So great indeed has been the interest in some specialized topics that three special sessions will be held, devoted respectively to the history of medicine, to physical medicine and to allergy. These sessions are held as part of the temporary Section on Miscellaneous Topics.

Well under way as a significant feature of the celebration of the centennial is the utilization of Sunday, June 8, as a special public health day. A religious program is being arranged with representatives of the leading faiths of our country. This will be held in the great auditorium in Convention Hall and will no doubt be broadcast on one of the national chains. At the same time congregations assembled for religious services elsewhere throughout the nation will be given messages regarding the advancement of medical science and the improvement in the public health that have occurred during the hundred year period.

The division of motion pictures in the headquarters office of the American Medical Association is at present engaged in the development of two motion pictures dealing with the lives of the distinguished American physicians of the period concerned and with the evolution of motion pictures in medical teaching. The first public showings are contemplated for Monday evening, June 9, in the large auditorium.

So great is the demand for space in the Scientific Exhibit and in the Technical Exhibits that it has been necessary to devote all the available space in Convention Hall for this purpose. Most exhibits will have historical themes. The meetings of the scientific sections will be assigned to the assembly halls in the numerous excellent hotels of the convention city. These hotels are all within walking distance of the great convention hall.

The President's Reception, which is an important feature of each annual session, will be held on this occasion in the music hall of Convention Hall, which provides facilities for an attendance of many thousands. The distinguished foreign guests, as well as the officers of the American Medical Association, will on that occasion be honored at the reception, and music will be provided by one of the leading orchestras of the nation.

The plans here announced represent but a beginning on some of the many features that are contemplated as part of the celebration of one hundred years of progress in American medicine, associated with the foundation of the American Medical Association in May 1847. The first instalment of a history of the American Medical Association, to be published in 1947, appears in this issue of The Journal. From the small beginning there reflected has come the great organization which now includes almost 130,000 members with its own properties, its many periodicals, its innumerable services to the medical profession, its councils, bureaus and other agencies devoted to the advancement of medicine and the improvement of the public health.

GERSON'S CANCER TREATMENT

Some years ago a technic called the Gerson, Sauerbruch-Hermannsdorfer diet was claimed to be a notable advance in the treatment of tuberculosis. Gerson proposed, by the use of these diets, to change the nature of the soil in which the tubercle bacillus lives. According to the reports, Gerson had discovered accidentally some improvement in a patient with lupus who was on a salt free diet. The good results in many types of tuberculosis reported by Gerson were apparently not susceptible of duplication by most other observers.

Dr. Max Bernhard Gerson, according to our records, was born in Wongrowitz, Germany, Oct. 18, 1881 and was graduated by the Albert-Ludwigs-Universtät Medizinische Fakultät, Freiburg, Baden, Germany, in 1909. He was licensed in New York in 1938 and, according to the records of the American Medical Association, is today at 667 Madison Avenue, New York, credited with being a member of the Medical Society of the State of New York. For several years now THE JOURNAL has been receiving requests from people all over the United States for information about Dr. Max Gerson, who is said to be using a dietary and salt controlled method for treating cancer patients at the Gotham Hospital in New York. THE JOURNAL has on several occasions requested Dr. Gerson to supply information as to the details of his method of treatment but has thus far received no satisfactory reply. A preliminary report, "Dietary Considerations in Malignant Neoplastic Diseases," appeared in the *Review of Gastroenterology*, November-December 1945, page 419.

In the meantime occasional references have appeared in the press to the Robinson Foundation for cancer research, located at 14 Wall Street, New York, which is said to be supporting the Gerson method. In the last session of Congress hearings were held on a bill to appropriate $100,000,000 of federal money for research on cancer. Dr. Gerson is said to have presented 5 of his patients to these public hearings. Fortunately for the American people this presentation received little, if any, newspaper publicity. However, Raymond Swing, radio commentator, in a broadcast over A. B. C. July 3, 1946 told the world that the Gerson cancer treatment was producing remarkable results. People who sent for a copy of the broadcast were referred to Dr. George Wiley at the Gotham Hospital.

Now there has come to hand through a prospective patient of Dr. Max Gerson a schedule of diets alleged to be beneficial in such cases. The patient was a man aged 83, with cancer of the stomach and multiple metastases, whom Dr. Gerson had never seen. Nevertheless he provided a complete diet for a period of four weeks, given in minute detail. The diet, which resembles that given in the *Review of Gastroenterology* forbade tobacco, spices, coffee, tea, chocolate, alcohol, white sugar, white flour, pastries and sausages; in short, no canned, preserved, sulfured, frozen, smoked, salted, refined or bottled food. It specified that there must be no salt, soda, sodium bicarbonate, fats or oil. It forbade also for some time the use of meat, fish, eggs, milk, butter, cheese and bread. It permitted fruit but nothing from cans. It specified a mixed fresh apple and carrot juice and other fruit juices and vegetables all freshly prepared and saltless. It forbade the use of aluminum utensils and pots, and it forbade the use of pressure cookers. Basis of the diet was a special soup, of which the unfortunate victim is supposed to take 1 quart a day. The formula included a large parsley root, 3 or 4 leeks, 1 large celery knob, 4 or 5 tomatoes, 3 to 5 large potatoes, 2 or 3 large onions and 3 to 5 carrots. Also permitted was some oatmeal. The medication included Lugol's solution daily, niacin in large amounts daily, liver powder with iron daily, lubile—dried bile salts—one capsule four times a day, brewers' yeast three times daily, dicalcium phosphate with viosterol one tablet eight times a day, phosphorus compound 1 teaspoon dissolved in each glass of juice, 3 cc. of crude liver extract intramuscularly several times a week and also some injected vitamin K. The formula says that there should be no other medication because it can be harmful and dangerous, and it warns particularly against the use of anesthesia, because it says that the body becomes highly hypersensitive through this diet and that the usual anesthesia might become fatal. As a part of the routine Dr. Gerson insists that a patient have at least one copious bowel movement a day, preferably two, and he has provided a formula for an enema to secure this activity.

Early in October the Chicago *Tribune* called attention to the Robinson Foundation, which apparently finances itself by manufacturing electric wire and cable and building life boats and marine equipment. The foundation was established in 1941 but did not qualify for exemption under section 1016 of the revenue code until 1944. Incidentally, a considerable number of similar foundations associated with large industrial concerns have appeared on the medical horizon in recent years. According to Mr. George P. Robinson, president of the foundation, it first sought to finance its activities by contributions. Later the foundation acquired four small manufacturing plants owned by corporations. These were dissolved, and their facilities were operated as divisions of the foundation. Two of the corporations were sold. Those still owned are the Hatfield Wire and Cable Company of Hillside, N. J., and Wellin Davit and Boat Company of Amboy, N. J. Mr. Robinson said, according to the Chicago *Tribune*, that the manufacturing divisions are managed as if they were separate corporate entities and are operated as competitive business enterprises. They pay unemployment insurance, local and state taxes and provide for depreciation, but they qualify for federal tax exemption by conforming their operations to the provision of the revenue code as does a college. Among the members of the foundation's advisory committee are listed Charles Seymour, Harlow Shapley, Raymond Swing, Matthew Woll and W. Cameron Forbes. Irving Fisher, professor of economics at Yale University, is listed as the director in charge of the foundation's section on health education.

Without any further investigation it would appear that a technic has developed whereby industrial corporations may incorporate themselves as research foundations and thus be free from federal income tax, since their profits are given to research in various medical fields. The intimate details of the conduct of these foundations are not open for public inspection, and Mr. George P. Robinson, when questioned, declined to disclose the earnings of the foundation that he represents. Similar foundations have been established in New York and in Washington. One corporation formed by the alumni of New York University acquired ownership of a piston ring manufacturing company, the untaxed profits of which are turned over to the university.

In the present instance the Robinson Foundation seems to be devoted to the promotion of an unestablished, somewhat questionable method of treating cancer. The only statements as to the number of patients treated, the number benefited and the possible effects of the treatment is that in the *Review of Gastroenterology* already cited. It offers clinical impressions as to benefits secured but nothing resembling scientific evidence as to the actual merit of the method. Indeed, it admits lack of any actual cure, claiming only that patients seemed improved in health and that some tumors were delayed in growth or became smaller. The entire performance, including the financial backing, the promotion and the scientific reports, has a peculiar effluvium which, to say the least, is distasteful and, at its worst, creates doubt and suspicion.

TRANSMISSION OF PRIMARY ATYPICAL PNEUMONIA TO VOLUNTEERS

During 1943 and 1944 studies on the transmissibility of primary atypical pneumonia were conducted on a group of conscientious objectors. The purpose of the studies was to determine whether atypical pneumonia could be transmitted with secretions of the respiratory tract of patients, whether the disease so produced resembled the naturally acquired infection and, finally, whether the disease could be induced by bacteria-free filtrates. Three groups of experiments were conducted, the first in October 1943 and the second and third during the summer of 1944.

The results of the second two experiments have been recently summarized in a series of reports[1] emanating from the Commission on Acute Respiratory Diseases. In the first of these, 36 men between the ages of 19 and 45 were selected after clinical and roentgenographic examination had shown that they were free from organic or infectious disease. All the volunteers were isolated and observed for three weeks prior to inoculation. The material inoculated into the volunteers was obtained from the throat washings and sputum of 7 patients with atypical pneumonia who had been admitted to the wards of the Regional Hospital at Fort Bragg during the previous two months. Before inoculation each volunteer was assigned to one of three groups, each group containing 12 men. One group received pooled material which had been filtered through Corning sintered glass or Seitz filters. Another group received material which had been autoclaved at 15 pounds pressure for ten minutes, and the third group received inoculum which had been untreated.

The final experiment differed only in that the volunteer group had been enlarged to 42 men, a few changes were made in the method of segregation of volunteers within the hotel, and the inoculum was administered outdoors and on separate days. There was also a slight difference in the origin of passage material, that is, the material for inoculation had been obtained from 6 cases of atypical pneumonia which had been experimentally induced. In the experiment in which 36 volunteers were involved, 10 became ill with what was classified as atypical pneumonia; 4 had received the filtered inoculum, 3 the autoclaved inoculum and 3 untreated material. In the final experiment involving 42 volunteers, 6 developed characteristic signs of atypical pneumonia; none of 18 who received the autoclaved inoculum became ill, but 3 who received the filtered inoculum and 3 the untreated inoculum developed the disease. In addition to atypical pneumonia, 15 of the first group and 11 of the second group developed minor respiratory illness of an undifferentiated type, thus suggesting a relationship between this group of diseases and atypical pneumonia.

In those cases in which atypical pneumonia developed as a result of experimental inoculation the incubation period was approximately one week in those who received untreated inoculum. In the 16 volunteers who developed the clinical features of atypical pneumonia the symptomatology, physical findings, roentgenographic pattern and clinical course were similar to the naturally acquired infection. An insidious onset is characteristic. The physical signs included moderate inflammatory changes in the upper respiratory tract and varying degrees of infiltration of the lungs.

As in the naturally occurring infection, examples of mild, moderately severe and severe forms of atypical pneumonia were observed. Of the 16 who developed atypical pneumonia 2 had severe illnesses associated with extensive infiltration of the lungs, and an additional patient showed disorientation and emotional instability. Recovery, however, occurred in all patients, though it was more prolonged in those who were severely ill than in the others.

---

[1] Commission on Acute Respiratory Diseases, Fort Bragg, North Carolina: The Transmission of Primary Atypical Pneumonia to Human Volunteers, Bull. Johns Hopkins Hosp. **79:** 97 (Aug.) 1946.

Laboratory studies were carried out on all the volunteers who developed primary atypical pneumonia and on the 26 inoculated persons who developed minor respiratory illnesses. Apparently the only significant change was a rise in titer of cold hemagglutinins, which occurred in 13 of the 16 cases of atypical pneumonia and in 11 of the 26 cases of minor respiratory illness.

These extensive and significant studies indicate that primary atypical pneumonia can be produced, though not invariably, by artificial transmission. The evidence indicates that the causative agent is filtrable, since nearly as high a proportion of cases developed following the use of a filtered inoculum as from the untreated material. On the basis of present knowledge there seems to be no difference between what is called primary atypical pneumonia and virus pneumonia. Furthermore, although evidence was not obtained indicating a relation between atypical pneumonia and influenza A or influenza B, it seems likely that many cases of minor respiratory illness occurring coincidentally with atypical pneumonia may be caused by the same etiologic agent.

Current Comment

NEW PLAN FOR REGISTERING FELLOWS IN ADVANCE OF THE ANNUAL A. M. A. SESSION.

At the suggestion and under the direction of the Board of Trustees, a plan is being developed for advance registration of Fellows who will attend the Ninety-Seventh Annual Session in Atlantic City, June 9-13, 1947. Arrangements have been made with the Housing Committee in Atlantic City to supply the headquarters office with duplicate slips of hotel room confirmations. These will be taken as evidence of proposed attendance at the session. The A. M. A. office in turn will send a letter and advance registration blank for immediate execution to Fellows who have made their hotel reservations. The registration form will be serially numbered, and this number will tally with that on an identification card that will be mailed to Fellows in return for the filled-in advance registration. The identification card is to be preserved and brought to the meeting. The identification card when presented at the proper window of the Registration Bureau in the Atlantic City convention hall will enable the clerk to supply, in a matter of seconds, the official Fellow's badge of admission to the scientific and social functions, program and lapel button for guest or guests. Any Fellow or Member planning to attend the meeting, but who will not have or need a hotel room in Atlantic City should write also to the American Medical Association, 535 North Dearborn Street, Chicago 10, for an advance registration blank. The 1947 session, which will commemorate the one hundredth anniversary of the American Medical Association, is attracting an exceedingly large attendance. Fellows will appreciate the convenience and saving of time to be experienced by this proposed advance registration.

SALMONELLA PULLORUM

In a period of three days in August 1945 at least 423 members of several squadrons at an army air base became ill[1] and 172 of them required hospitalization. The total number affected was larger, as some whose symptoms were mild did not appear at sick call. In the hospitalized patients the symptoms, in order of frequency, were fever (average 102, in some 105 F.), *diarrhea, headache, abdominal cramps, chills, nausea,* vomiting, myalgia, prostration and backache. All patients recovered and were discharged from the hospital by the end of the third day. However, the military importance of the outbreak is obvious. An investigation was made by the Central Diarrheal Disease Control Laboratory of the School of Aviation Medicine, Randolph Field, Texas, but the unit did not arrive at the base until the patients were recovering from the acute phase of the illness. Nevertheless the general mess where these squadrons ate their meals was promptly implicated and it was found that a rice pudding into which raw chicken eggs and canned milk had been mixed was the only food eaten by practically all of the patients. As it was, Salmonella pullorum was isolated from the stools of 11.7 per cent of the hospital patients; Salmonella derby was obtained from 1 patient (0.6 per cent). Other pathogens were not found, nor were salmonella cultures obtained from any of the healthy mess attendants. The anal swab technic was used, the swabs being plated directly and also after preliminary enrichment. Cultures were thus made from all but 1 of the hospital patients and from all of the healthy mess attendants. While the facts brought out were necessarily not complete, after careful consideration of various etiologic possibilities it was concluded that Salmonella pullorum was the active agent of the outbreak. Salmonella pullorum, a familiar cause of disease in chickens, is known to be present in the eggs of infected fowls. Usually described as not pathogenic for man, it has never before, as far as the authors know, been incriminated as the cause of a definite outbreak of food poisoning. The importance of determining its role as a human pathogen, however, had previously been emphasized.[2] The more recent evidence further serves to make necessary reconsideration of the role of this organism as a human pathogen and to warn against the use as food of raw eggs and egg products infected with Salmonella pullorum.

ORGANIZATION SECTION

Official Notes

RESOLUTIONS TO BE PRESENTED TO HOUSE OF DELEGATES

NOTE—These resolutions are published in accordance with a request of the House of Delegates to the effect that resolutions to be presented before the House of Delegates be published thirty days before the House of Delegates is to convene in session

These resolutions were adopted by the Michigan State Medical Society:

Resolutions on Establishment of General Practice Sections in Approved Hospitals

WHEREAS, The House of Delegates of the American Medical Association has established an individual section on the General Practice of Medicine, and

WHEREAS, The General Practitioner has been recognized as a separate branch in the medical profession, and

WHEREAS, This group has shown its interest in this section by registering 939 members in the section at the 1946 American Medical Association meeting in San Francisco, and

WHEREAS, Their scientific section meetings were well attended; and

WHEREAS, The House of Delegates has already voiced its approval of such sections in the separate state and county societies that are component parts of the American Medical Association, and

WHEREAS, Sections on General Practice have been started in some recognized hospitals that are approved by the American College of Surgeons and Council on Medical Education and Hospitals and have been accepted by those bodies, and

WHEREAS, Many hospitals have not established General Practice sections in their visiting active staffs, and their governing heads are doubtful whether such action has the approval of the bodies which set up the rules and regulations for the approval of their hospitals for interns and residents; therefore be it

Resolved, That the Delegates of the Michigan State Medical Society in convention assembled voice their approval of the establishment of Sections on General Practice in approved hospitals and that the Delegates from Michigan to the American Medical Association House of Delegates introduce a similar resolution at the next meeting, requesting approval of that body; and be it further

Resolved, That a copy of this resolution be sent to the Hospital Committee of the American College of Surgeons with a request that this body voice approval of such sections and include such in its Manual of Hospital Regulations

Resolution on American Medical Association Contribution to Health Education Projects

WHEREAS, The Michigan State Medical Society has supported a program of Health Education during the past five years; and

WHEREAS, Such Health Education is not purely of local but also of national interest and value, therefore be it

Resolved, That the delegates of the Michigan State Medical Society to the American Medical Association be instructed to initiate a study of a policy by which the American Medical Association can contribute a portion of the cost of such a program of Health Education carried on by any state medical society.

A. M. A.-N. B. C. CENTENNIAL BROADCASTS

In celebration of the centennial year of the American Medical Association, 1947, the twelfth annual series of the A. M. A - N. B. C. dramatized broadcasts will be devoted to features of medical progress in the United States during the hundred years of the existence of the American Medical Association

For purposes of the broadcast, the United States will be divided into twenty-five regions as shown in the accompanying map. These regions have been chosen with a view to grouping together states which have a similar history and similar general characteristics, such as, for example, the four states of the Rocky Mountain region, the two groups of New England states, and the Southeastern and the Central Southern groups.

One broadcast will be devoted to medical progress in each twenty-sixth and closing week will deal with the hundred years of the American Medical Association from a nationwide standpoint.

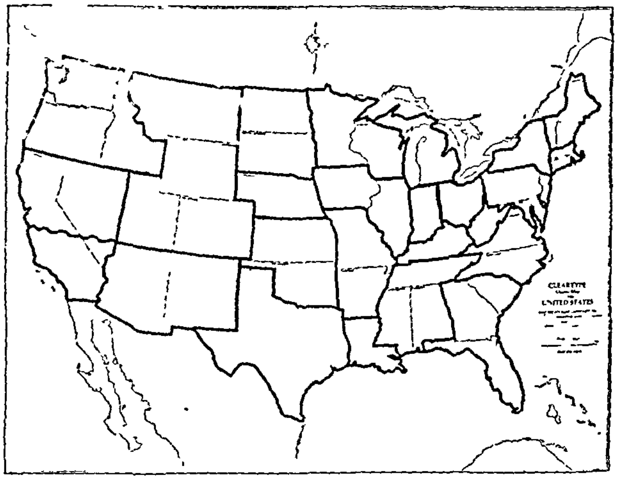
Each broadcast will be divided into two parts. The first part will consist of a dramatization dealing with historic physicians and medical events in the region. This will be broadcast from Chicago.. The first part of the program will take approximately twenty-three minutes.

For part two of the program we will switch from Chicago to a radio station to be designated in each of the twenty-five regional areas. From this station a three minute broadcast will be made by a speaker representing the medical societies in that area

State medical societies have been requested to furnish historical material and to nominate speakers. All have now responded and are in the process of making material available.

An effort will be made to announce in THE JOURNAL from week to week the date for each regional broadcast The sequence will be determined by the order in which materials are received from state medical societies.

It is hoped that each state medical society will give wide publicity to its regional broadcast within its own borders. Such publicity can be by local radio broadcasts, newspaper publicity, posters or newspaper advertising.



Published with permission of the American Map Company.

Twenty five regions into which states have been grouped.

The title for the series will be "Doctors—Then and Now," and the theme will be "A Century of Progress by American Medicine."

The dramatic scripts will be written by William J. Murphy, veteran medical script writer responsible for most of the previous A. M. A. - N. B. C. series; production will be directed by Norman Felton, director of the two preceding series; Joseph Gallicchio will again direct the N. B. C. orchestra. Arrangements with N. B C. have been made through the office of Miss Judith Waller, Public Service Director, Central Division, National Broadcasting Company.

The first four dates with topics are as follows: Dec. 7, 1946 Alabama, Mississippi and Tennessee; subject James Marion Sims; the speaker, to be announced, will broadcast from station WSM, Nashville. Dec. 14, 1946 Kansas and Oklahoma; subject Dr Samuel J. Crumbine; speaker Dr. L J. Moorman, who will speak from station WKY at Oklahoma City. Dec. 21, 1946 no broadcast Dec. 28, 1946 Minnesota and Wisconsin; subject William Beaumont; speaker Dr. William A O'Brien, who will speak from station KSTP at St. Paul.

The program will be broadcast from 3 to 3:30 p. m.. central standard time

Subsequent programs will be announced as soon as they are ready.

MEDICINE AND EDUCATION TEAM UP FOR HEALTH AND PHYSICAL FITNESS

The appointment of Dr. Dean F. Smiley and Mr. Fred V. Hein as consultants in health and physical fitness, on the staff of the Bureau of Health Education of the American Medical Association, is announced.

Dr. Smiley, recently a commander in the U. S. Navy, who will function as the medical adviser of the team, received both his A.B. and M.D. degrees at Cornell University. He has had a broad experience in preventive medicine and in all aspects of health education at Cornell University, in the New York State Education Department and as director of the medical aspects of audiovisual education in the U. S. Navy. Dr. Smiley has served as secretary and president of the American Student Health Association, is a member of the Committee on Motion Pictures of the American Medical Association and is a fellow of the American Public Health Association. He has written widely for professional magazines and is co-author of numerous books in the health field, among the most widely known of which are "A College Textbook of Hygiene," "Community Hygiene" and the "Health and Growth Series." Dr. Smiley also was a member of the investigating committee for the Carnegie Foundation for the Advancement of Teaching in its inquiry into school and college athletics.

Fred V. Hein, the educational consultant, comes directly from the public school field. He attended La Crosse State Teachers College, received his Ph.B. from Ripon College, the M.S. degree from the University of Wisconsin, and he expects to receive his Ph.D. from the same institution in the near future. Mr. Hein has taught all phases of health and physical education from the elementary through the college level and for the last eight years has been director of health and physical education in the public schools of Oshkosh, Wis. During the war he served as director of the Physical Training Program for the Army Air Corps unit at the Oshkosh State Teachers College and has lately been a visiting lecturer at the University of Wisconsin. Mr. Hein is a past president of the Wisconsin Health and Physical Education Association and has served as chairman of various sections of the Midwest Physical Education Society. He is a contributor to periodicals in the field and has recently completed his doctor's dissertation in the area of interpreting the program to the home and the community.

Coming Medical Meetings

American Medical Association House of Delegates Supplemental Session, Chicago, Dec. 9-11. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Conference of State Secretaries and Editors, Chicago, Dec. 7-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Allergy, New York, Nov. 25-27. Dr. Karl D. Figley, 316 Michigan St., Toledo 2, Ohio, Secretary.

American Academy of Dermatology and Syphilology, Cleveland, Dec. 7-12. Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, N. Y., Secretary.

American College of Surgeons, Cleveland, Dec. 16-20. Dr. Dallas B. Phemister, 40 E. Erie St., Chicago 11, Secretary.

American Society of Anesthesiologists, New York, Dec. 12. Dr. Curtiss B. Hickcox, 745 Fifth Ave., Room 1503, New York, Secretary.

National Society for the Prevention of Blindness, New York, Nov. 25-27. Mrs. Eleanor Brown Merrill, 1790 Broadway, New York 19, Executive Director.

Post Graduate Medical Assembly of South Texas, Houston, Dec. 3-5. Dr. M. B. Stokes, 229 Medical Arts Bldg., Houston, Secretary.

Puerto Rico, Medical Association of, Santurce, Dec. 13-15. Dr. Rafael A. Vilar, P. O. Box 3866, Santurce, Secretary.

Radiological Society of North America, Chicago, Dec. 1-6. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse 2, N. Y., Secretary.

Society of Surgeons of New Jersey, Newark, Nov. 20. Dr. Walter B. Mount, 21 Plymouth St., Montclair, Secretary.

Southern Surgical Association, Hot Springs, Va., Dec. 10-12. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Western Surgical Association, Memphis, Tenn., Dec. 5-7. Dr. Warren H. Cole, 1853 W. Polk St.; Chicago 12, Secretary.

Washington Letter

(From a Special Correspondent)

Nov. 11, 1946.

Republican Stand on Medical Legislation

Proponents of socialized medicine were expected to have less success in winning consideration of their legislation with the Republican party having won majorities both in the House and in the Senate. G. O. P. leaders have already expressed their opposition to enactment of bills advanced by advocates of socialized medicine. Not only will the eightieth Congress have many new faces in both houses but there will be extensive changes in committee lineups due to the reduction in the number of committees from forty-eight to nineteen in the House and from thirty-three to fifteen in the Senate. Republicans have indicated that they propose to accept the congressional streamlining passed at the last session. It will be adopted on a trial basis.

Public Health Officials Advised to get Support of Businessmen

Howard Strong of the Chamber of Commerce of the United States advised public health officials to get the aid of businessmen to secure enactment of health programs when he addressed a one day conference held by the Metropolitan Washington Tuberculosis Conference. Mr. Strong said "Citizens usually discount the need for a public health program when advanced by public health officials, but if businessmen get behind it the idea goes over much better." The use of streptomycin in the treatment of tuberculosis and the nursing problem were among other subjects discussed by the 250 delegates, which included public health officials, doctors, nurses and laymen interested in the treatment of tuberculosis.

Eight Thousand Amputees Apply for Specially Equipped Automobiles from Congress

The Veterans Administration has announced that 8,000 disabled veterans have applied for automobiles under the legislation signed by President Truman on August 8 whereby veterans who lost the use of one or both legs at or above the ankle are entitled to free cars. Only 75 cars have been delivered so far. The War Assets Administration has also made military typewriters available to disabled patients at Walter Reed General and Bethesda Naval hospitals for $20 and $25 each. Four categories of patients may apply for the typewriters: amputees, the paraplegic, the tuberculous and others facing extended hospitalization or future restrictions to sedentary work.

General Erskine Asks Jurisdiction Over Artificial Limb Industry

Major Gen. G. B. Erskine, director of veteran reemployment and retraining, has asked John Steelman, reconversion director, for jurisdiction over the manufacture and distribution of artificial limbs. Amputees, he says, complain that publicized "improvements" in artificial limbs have not reached the production stage. Mr. Steelman has not yet replied to General Erskine's request for authority to assist the Committee on Prosthetic Devices and independent manufacturers to translate research into production, for a training program for limb mechanics and fitters, and for establishing standards for the prosthetic appliance field.

Cancer Council Approves $225,000 in Research Grants

The National Advisory Cancer Council has announced that it has approved grants in aid totaling $225,000 to twenty universities, hospitals and research units. Twenty-four physicians, representing fourteen medical schools, met with the council to plan a medical education program against cancer, second disease in the cause of death in the United States. Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, said that more comprehensive and better integrated courses in cancer at medical schools were considered.

Winner of Women's Medical Association Award Completes Study Here

Dr. Alicia Galaga Romero of Mexico City, first winner of the American Women's Medical Association fellowship award to foreign women physicians, has completed her year of study in this country, at Children's Hospital here. She has returned to her home city as a specialist in children's diseases.

GOVERNMENT SERVICES

ARMY

APPOINT MORE CIVILIAN CONSULTANTS

The War Department announced October 21 the appointment through the Surgeon General of 122 civilian medical consultants to the Secretary of War. This brings the total of civilian consultants available to the Army Medical Department to 327. Some 70,000 patients are in army hospitals throughout the world.

James H. Kidder, New York, dean of the College of Pharmacy, Fordham University, was named as consultant to the Surgeon General to advise on matters relating to pharmacy.

Those whose appointments were announced are:

Internal Medicine

Daniel H. Autry, Little Rock, Ark.
William W. Bondurant Jr., San *Antonio, Texas.*
Bruce P. Webster, New York.
Sam A. Overstreet, Louisville, Ky.
William H. Higgins, Richmond, Va.
John W. Brown, San Francisco.
Dwight L. Wilbur, San Francisco.
Edwin G. Bannick, Seattle.
Frank R. Maddison, Tacoma, Wash.
Treacy H. Duerfeldt, Tacoma, Wash.
James W. Haviland, Tacoma, Wash.
Verne R. Mason, Los Angeles.
Charles F. Wilkinson Jr., Ann Arbor, Mich.
Donald F. Marion, Coral Gables, Fla.
Jack O. W. Rash, Miami, Fla.
Franz H. Stewart, Miami, Fla.
Howard L. Alt, Evanston, Ill.
Marion H. Barker, Chicago.
Neil L. Crone, Belmont, Mass.
Perrin H. Long, Baltimore.
William D. Province, Franklin, Ind.
Robert C. Kimbrough Jr., Ann Arbor, Mich.
Henry M. Winans, Dallas, Texas.
Johnson McGuire, Cincinnati.
Arthur N. Ferguson, Fort Wayne, Ind.

Dermatology-Syphilology

George V. Kulchar, San Francisco.
Howard Hailey, Atlanta, Ga.
Clarence S. Livingood, Philadelphia.
Donald M. Pillsbury, Philadelphia.

Dermatology

Edward A. Levin, San Francisco.

Pediatrics

John A. Washington, Washington, D. C.
Harry H. Gordon, New York.

Physical Medicine

Frank H. Krusen, Rochester, Minn.
Kristian G. Hansson, New York.
Richard L. Kovacs, New York.

General Surgery

Robert T. Allison Jr., Akron, Ohio.
Thomas A. Botsford, Brookline, Mass.
Roscoe C. Giles, Chicago.
John A. Hardy, El Paso, Texas.
Siegfried F. Hermann, Tacoma, Wash.
George D. Lilly, Miami, Fla.
Thomas B. Quigley, Boston.
Fred W. Rankin, Lexington, Ky.

Otolaryngology

Hallowell Davis, St. Louis.
S. Richard Silverman, St. Louis.
Albert C. Furstenberg, Ann Arbor, Mich.
Mercer G. Lynch, New Orleans.
M. P. S. Spearman, El Paso, Texas.

Radiology

William E. Allen Jr., St. Louis.
Edgar M. McPeak, Washington, D. C.
Ernst A. Schmidt, Denver.

Orthopedics

Edward W. Cullipher, Miami, Fla.
Louis H. Edmunds, Seattle.
William H. Goering, Tacoma, Wash.
Robert P. Kelly, Atlanta, Ga.

Aural Rehabilitation

Grant Fairbanks, Los Angeles.

Neurosurgery

Frank W. Lusignan, San Francisco.

Obstetrics and Gynecology

Carlton N. Price, Washington, D. C.

Urology

Burton L. Stewart, North Hollywood, Calif.
William A. Sumner, San Francisco.

Plans and Operations

Eli Ginsberg, Ph.D., statistician, New York.
Mr. Jarrett White, real estate and hospital construction adviser, Washington, D. C.

Neuropsychiatry

Titus H. Harris, Galveston, Texas.
Martin L. Towler, Galveston, Texas.

Albert B. Sabin, Cincinnati.
Jonas E. Salk, Ann Arbor, Mich.
Joseph Stokes Jr., Philadelphia.

FLIGHT NURSES

Twelve officers of the Army Nurses Corps graduated from the Army Air Forces School of Aviation Medicine at Randolph Field, Texas, on October 25 as flight nurses. These carefully selected volunteer nurses came to the school for an intensive nine weeks' training course, the first five of which were given over to basic military medical and surgical subjects and the final four weeks to actual air evacuation flights in the United States. On certification of the commanding general, Army Air Forces, the graduates are authorized to wear the distinctive wings of the Army Air Force Flight Nurses.

THE ARMY NEEDS PSYCHIATRIC SOCIAL WORKERS

In a War Department announcement, October 18, Major Gen. Norman T. Kirk, the Surgeon General, urged that officers and former officers qualified in psychiatric social work make application for integration into the Regular Army. Officers are eligible whether on active duty or not and regardless of their branch of service. Officers awarded commissions will receive them temporarily in the Pharmacy Corps.

Psychiatric social workers are needed to augment neuropsychiatrists. Former A. U. S. officers may apply for commission in the Pharmacy Corps as technical specialists in psychiatric social work. Appointments will be made in grades from 2d lieutenant through major in a grade not higher than that held during wartime. Applicants appointed who are now enlisted men or warrant officers will be discharged for the convenience of the government to accept commissions in the Regular Army. As this is an interim measure, special educational requirements for the Pharmacy Corps are waived. College graduates with a degree acceptable to the Surgeon General, which will basically qualify the officer for further training in psychiatric social work, will be acceptable for integration into the Pharmacy Corps. For initial classification as a psychiatric social worker the applicant must have completed at least one year of training in an accredited school of social work, including supervised field work and one year social case work experience in a health or welfare agency of acceptable standards.

Applications must be forwarded prior to Dec. 31, 1946. Formal applications, in triplicate, will be made on WD AGO Form 62 (Sept. 1, 1946) and forwarded to the Commanding General of the Army area in which the applicant resides.

OCHSNER MEDICAL FOUNDATION PURCHASES STATION HOSPITAL

The offer of the Alton Ochsner Medical Foundation to purchase the station hospital at Camp Plauche, Louisiana, for $150,000 has been approved by the War Assets Administration. The foundation proposes to establish a 625 bed hospital, of which it is planned that 300 beds will be for patients originating through the Ochsner Clinic, 25 beds for charity purposes supported by funds of the Ochsner Foundation, and 300 beds to establish an amputation center primarily for veterans of World War II. It is also anticipated that a school for teaching veteran amputees will be established in the hospital as well as facilities for servicing and testing of artificial limbs. The present staff of the foundation consists of 81 doctors, of whom 46 are veterans, 26 of the group being in training for special amputee work.

The installation at Camp Plauche consists of 111 temporary frame buildings on 86.56 acres of leased land. The transaction will include all the medical equipment and supplies now in the hospital which are essential to the proposed plan of operation, with the exception of certain items of dental equipment.

MEDICAL CARDS AVAILABLE TO LIBRARIES

Beginning October 1, entries prepared by the Army Medical Library will be printed and made available for distribution by the Library of Congress. These entries will vary from the present Library of Congress cards in some details. They will carry the subject heads and new classification numbers of the Army Medical Library. Subscriptions to the series should be placed with the Card Divisions of the Library of Congress, to which all inquiries regarding these cards should be addressed.

PERSONALS

Mr. Robert B. Austin has been appointed acting head of the Cleveland branch of the Army Medical Library to succeed Dr. Max H. Fisch, who has accepted a professorship at the University of Illinois. Mr. Austin has been with the Army Medical Library in various capacities since 1928.

AN INTENSIVE FOOD RESEARCH PROGRAM

Eighty colleges, universities and other agencies are collaborating with the Quartermaster Corps in a comprehensive research program designed to evaluate and improve the nutritional and physiologic adequacy and the acceptability of rations for use under operational conditions, to improve the functional characteristics of food and to investigate the chemical and microbiologic factors which affect the stability of foods and rations for the Army.

The program is sponsored by a Committee on Research which includes Emil Mrak, associate professor, division of food technology, University of California; Dr. W. F. Geddes, chief, division of agricultural biochemistry, University of Minnesota; Dr. H. E. Longnecker, dean, graduate school, University of Pittsburgh; Dr. George F. Steward, research professor, poultry husbandry, Iowa State College; Dr. George Gelman, technical director of the Quartermaster Food and Container Institute of the Armed Forces, and Dr. M. L. Anson, director of chemical research, Continental Foods, Inc. The center of this comprehensive program is the Quartermaster Food and Container Institute at Chicago. The program has been divided into more than a hundred research projects.

Col. Charles S. Lawrence, commanding officer of the Food and Container Institute, points out that acceptability of foods by soldiers is of utmost importance in military feeding. The problem of optimum acceptability, Colonel Lawrence says, is a complicated one for the civilian populations, but for the military these complications are increased many fold. Superimposed on these difficulties are environmental factors such as feeding under assault, combat, survival and support conditions; the effects of climate and of physiologic and psychologic factors; allergies; food habits, and numerous other factors.

A scientific advisory board serves to bring to the attention of the Committee on Food Research specific problems having military implications which require fundamental research, and the board assists in translating these problems into fundamental research. Members of the advisory board are Dr. George Berryman, director of research, Medical Nutrition Laboratory, U. S. Army; Dr. S. M. Cantor, Corn Industries Research Foundation; Dr. Ralph M. Conrad, director Bureau of Industrial Research, University of Denver; Dr. H. C. Diehl, director, the Refrigeration Research Foundation, Inc.; Dr. W. Franklin Dove, chief, food acceptance branch, Food and Container Institute; Dr. C. G. King, director, Nutrition Research Foundation, Inc.; Dr. H. H. Kraybill, director of research, American Meat Institute; Dr. Samuel Lopkovsky, associate professor, plant pathology, Cornell University; Dr. O. B. Williams, professor and chairman, department of botany and bacteriology, University of Texas; Dr. Louis Howard, chief, Bureau of Agricultural and Industrial Chemistry, U. S. Department of Agriculture, and Dr. S. T. Coulter, professor, dairy husbandry, University of Minnesota.

ENLIST CERTAIN DISABLED VETERANS

The War Department has announced that certain categories of disabled veterans will be accepted for enlistment in the Regular Army in order to use their skills and also to offer the Army as a career to many heretofore barred because of disability caused by honorable service. The War Department has directed that an initial 5,000 partially disabled veterans will be accepted for service in the Regular Army. Careful study of the accomplishments and the development of special skills by partially disabled men has proved that they have equal value in many occupations to many other men unhindered by any handicap. Some of the positions listed by the War Department as those that can be filled by these individuals include x-ray technician, medical technician, dental assistant, medical laboratory technician, dental laboratory technician, pharmacy technician, clerk and stenographer. This action permits the War Department to accomplish materially within the Army the rehabilitation placement of certain disabled veterans, a program it has long sponsored in civilian placement.

Use of the disabled enlistee to fill the need for skilled manpower will allow the Army to release more physically fit soldiers for more strenuous duties.

NAVY

FULL TIME ACTIVE DUTY FOR NAVAL RESERVE OFFICERS

The Naval Air Reserve Training Command, Glenview, Ill., invites the attention of reserve medical officers and pharmacists of the Hospital Corps to the opportunity to perform full time active duty at one of the following major naval air stations or at one of the Naval Air Reserve training units:

Stations of the Naval Air Reserve Training Command:

NAS, Atlanta, Ga
NAS, Columbus, Ohio.
NAS, Dallas, Texas.
NAS, Glenview, Ill.
NAS, Grosse Ile, Mich.
NAS, Los Alamitos, Calif.
NAS, Memphis, Tenn.
NAS, Minneapolis.
NAS, New Orleans.
NAS, New York.
NAS, Oakland, Calif.
NAS, Olathe, Kan.
NAS, Squantum, Mass.
NAS, St. Louis.
NAS, Willow Grove, Pa.

Naval Air Reserve Training Units

These are based at the following Naval Air Stations:

Anacostia, D. C.
Jacksonville, Fla.
Miami, Fla.
Norfolk, Va.
San Diego, Calif.
Seattle.

Officers in the aforementioned category interested in full time active duty as a member of the stationkeeper staff at one of the stations or units listed should initiate letters to the Bureau of Naval Personnel via the Chief of Naval Air Reserve Training, Naval Air Station, Glenview, Ill., and BuMed, listing three or four stations at which duty is desired in order of preference. Personnel are desired in the ranks of commander and lieutenant commander in the Medical Corps.

Officers qualifying for these billets can be assured of every consideration in obtaining and continuing duty at the station of their preference. It is the policy of the command to obtain "orders to duty involving flying" for designated naval flight surgeons. Government quarters are available at many of the major naval air stations.

Naval flight surgeons of the reserve desirous of affiliating with the organized or volunteer components of the inactive reserve naval or marine air groups training at one of the naval air stations or Naval Air Reserve training units listed should communicate with the commanding officer of the station or the Naval Air Reserve training unit at which the training unit is based.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Francis H. McCullough

The Commendation Ribbon was recently awarded to Lieut. Francis H. McCullough (MC), U.S.N.R., Jackson Heights, N. Y., "for excellent service in the line of professional duties as medical officer aboard a United States destroyer when on April 6, 1945 he voluntarily boarded the U. S. S. *Morris*, which had been struck and left burning furiously by an enemy suicide plane during the amphibious assault and capture of Okinawa. In face of great danger from raging fires and imminent danger of explosion of the ship's magazines," continues the citation, "Dr. McCullough rendered invaluable professional assistance in the treatment of the numerous casualties. . . . As a result of his skill only 1 of the 43 seriously wounded men died." Dr. McCullough was graduated from Duke University School of Medicine, Durham, N. C., in 1943 and entered the service Oct. 1, 1944.

Commander Lawrence Stewart Bailey

The Commendation Ribbon was recently awarded to Comdr. Lawrence Stewart Bailey (MC), U.S.N.R., Zionsville, Ind., for distinguishing himself by excellent service as a senior medical officer of the Twenty-Second Special U. S. Naval Construction Battalion, in charge of malaria control for the battalion at U. S. Naval Base Manus from May 18, 1944 to July 31, 1945. "Through his professional skill, capable leadership and unremitting efforts," continued the commendations, "while located in an area in the southwest Pacific where malaria is prevalent, he successfully organized and maintained malaria control at such a high point of efficiency that no cases of malaria infection occurred within his battalion during a period of sixteen months. For his conduct throughout he is commended and authorized to wear the Commendation Ribbon." Dr. Bailey graduated from Indiana University School of Medicine, Bloomington-Indianapolis, and entered the service Sept. 3, 1942.

VETERANS ADMINISTRATION

STAFF APPOINTMENTS AT JEFFERSON BARRACKS HOSPITAL

The Dean's Committee has announced the appointment of 69 residents and attending and consultant physicians at the Veterans Hospital at Jefferson Barracks, Missouri. This committee, comprising four members from Washington University School of Medicine and four from the St. Louis University School of Medicine, is charged with administering the professional services at this hospital. The secretary of the Dean's Committee is Dr. Franklin E. Walton, associate professor of surgery at Washington University School of Medicine.

The attending and consultant physicians who receive appointments must be faculty members of one of the two medical schools, must have seen active war service and be members of their respective specialty boards. The residency appointments are for three years and will apply toward certification in the various specialties. This hospital has 727 beds and has been authorized by the Veterans Administration to establish an additional 500 beds.

PSYCHIATRIC CLINIC FOR VETERANS

The Mental Hygiene Society of Monroe County, Rochester, N. Y., and the Rochester chapter of the American Red Cross jointly sponsored a psychiatric clinic for veterans, which opened last June under the direction of Dr. George R. Lavine. The chief function is the diagnosis and treatment of veterans striving to adjust to civilian life and who present emotional problems for which psychiatric care is indicated. The president of the Mental Hygiene Society, Dr. William A. Sawyer, points out that the clinic is meeting a vital need and that 1947 promises to be an active year.

PERSONALS

Dr. Paul B. Magnuson, Chairman, Department of Bone and Joint Surgery, Northwestern University Medical School, Chicago, is acting assistant medical director for Research and Education, Veterans Administration, Washington, D. C. Dr. Magnuson is a founder-member of the American Board of Surgery, a member of numerous scientific organizations and a member of the Committee on Orthopedic Surgery of the National Research Council.

Dr. Maurice B. Strauss of Newtonville, Mass., formerly chief of medical service at Cushing (army) General Hospital, Framingham, will continue in the same capacity for the Veterans Administration, which took over that hospital October 1. Dr. Strauss served in the war in Hawaii, Saipan and Iwo Jima and was recently released from the army as a lieutenant colonel. He is an associate in medicine at Harvard Medical School and for many years was a member of the Thorndike Memorial Laboratory at the Boston City Hospital.

Dr. Montgomery A. Stuart of Annapolis, Md., a retired captain of the United States Navy Medical Corps, has been appointed to a position in the medical division of the Roanoke, Va., regional office of the Veterans Administration. He is a graduate of the Wayne University College of Medicine, Detroit, and during World War II served in San Juan, Puerto Rico, New York and Norfolk, Va.

PUBLIC HEALTH SERVICE

FELLOWSHIPS AVAILABLE IN MEDICAL RESEARCH

The United States Public Health Service, Washington, D. C., announces that about 120 one year fellowships in medical research are open to men and women who are graduate science students. These fellowships are part of the program of the National Institute of Health, a unit of the Public Health Service. Fellowships are open to graduates of accredited colleges who have majored in biology, chemistry, dentistry, entomology, physics and other scientific fields. Senior research fellowships awarded to those who hold Ph.D. degrees pay a yearly stipend of $3,000. Junior fellows who receive $2,400 a year must hold a master's degree in science or must have completed the equivalent of a master's degree in postgraduate study. The fellowship may be renewed for a second year. Applications should be sent to the Director, National Institute of Health, Bethesda, Md.

The National Cancer Institute, which operates as a division of the National Institute of Health, also has funds to train about thirty physicians in the diagnosis and treatment of cancer. Under a federally financed program, doctors who wish to specialize in this field may be appointed as trainees and be assigned to authorized nonfederal, nonprofit institutions in various parts of the country.

The Public Health Service also administers fellowships awarded by the state department to health personnel from other American republics and the Philippine Islands. One hundred fellowships will be available between now and the end of 1947 to qualified residents of the Philippines, and from fifteen to twenty fellowships, open through June 30, 1947, to professional persons from other American republics. Applications for these should be sent to the Surgeon General, United States Public Health Service, Washington 25, D. C.

DR. LEWIS R. THOMPSON RETIRES

After thirty-six years in the U. S. Public Health Service Dr. Lewis Thompson, Assistant Surgeon General in the Bureau of State Services, was retired for medical disability on November 1. Born in Indiana in 1883, Dr. Thompson received his M.D. degree from the Louisville Medical College and joined the Public Health Service as an assistant surgeon in 1910. He has been Assistant Surgeon General since 1930 and since 1943 has served as chief and associate chief of the Bureau of State Services. Dr. Thompson has served as scientific director of the International Health Division, Rockefeller Foundation, and as a member of the Division of Medical Sciences of the National Research Council. He was chief of the Medical Division of the U. S. Strategic Bombing Survey in Japan in 1945 and 1946. He organized the National Institute of Health and was its director for many years.

To fill the vacancy left by Dr. Thompson, Dr. Herman E. Hilleboe, who has been chief of the Tuberculosis Central Division since its inception in 1944, has been appointed associate chief of the Bureau of State Services with the rank of Assistant Surgeon General. Senior Surgeon Francis J. Weber, formerly assistant chief of the Tuberculosis Control Division, has been promoted to the rank of medical director and will serve as chief of the Tuberculosis Control Division.

MISCELLANEOUS

NATIONWIDE DRIVE FOR FUNDS FOR NURSES MEMORIAL

The chairman of the Nurses National Memorial, Arthur H. Johnson, announces an intensive nationwide drive, opening November 17 and continuing until shortly before Christmas, to raise $2,000,000 to build and endow a home and center in Washington, D. C., for nurses and medical women of the armed services. Contributions for the fund will be sought from American industry, business and finance and from citizens in all walks of life. Contributions will be gathered by local committees or sent to Nurses National Memorial Headquarters, Washington, D. C.

The Nurses National Memorial will benefit upward of 100,000 women who have served the armed forces. The home will have sleeping rooms for at least 300 women, an assembly room, library, complete kitchen and dining room facilities, class rooms and recreational rooms. Under a plan worked out, the nurses and medical women will enjoy the privileges of the home, paying only the actual cost of meals and room maintenance.

NEW BOARD TO CORRELATE GOVERNMENT SCIENTIFIC ACTIVITIES

President Truman set up on October 17 a new board to correlate the government activities in the field of science and named John R. Steelman to head the group, which will be known as the Presidential Research Board. This group is said to be an administrative substitute for the National Science Foundation, which, according to the Washington *Post*, was stymied in the closing days of the last Congress. The purpose of the new board is to insure that the scientific personnel, training and research facilities of the nation are used most effectively in the national interest.

Mr. Truman said, in part, in his executive order that the nation has a vast reservoir of war accelerated technologic development which must be applied speedily and effectively to the problems of peace, setting up productivity in both industry and agriculture, creation of new farm and factory products and advancement of medical science, and that in creating this board the groundwork is laid for a general plan designed to insure that federal scientific research will promote the most effective allocation of research resources between the universities, research foundations, industry and the federal government. Another objective of the board is to prevent expensive and inefficient overlapping of federal research work.

The twelve board members besides Mr. Steelman include cabinet officers and heads of various government agencies.

CHILDREN'S BUREAU PROJECTS

The Children's Bureau, Washington, D. C., announced on October 16, according to the New York *Times*, that in the near future several maternity care demonstration projects would be established, the first one at Tuskegee, Ala., made possible by appropriations voted by the last Congress under the Social Security Act. The purpose of these demonstrations, it was said, is "to show what might be done in getting comprehensive maternity care to a group of women who now often lack the most elementary care."

The committee of child specialists which recommended the establishment of the maternity care projects also recommended the establishment of blood banks in strategic centers for mothers needing emergency transfusions, providing chest x-ray examinations of all maternity patients to detect tuberculosis and other conditions early in pregnancy, providing funds to hospitals to care for prematurely born infants and setting up systems of care for crippled children who are victims of rheumatic fever, speech and hearing defects, epilepsy and chronic illnesses as well as the orthopedically handicapped.

The Children's Bureau is reported to have said that a team of five professional workers was appointed to travel round the country to visit cerebral palsy centers and that they will report to a national conference to be held at the Children's Bureau before the year ends. The committee recommended also the granting of training fellowships in mental health to teachers in order to offer more mental health services.

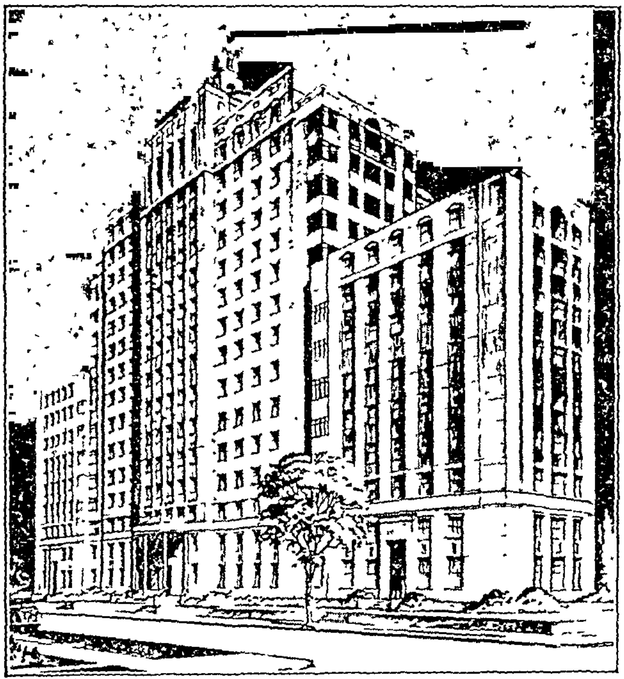
Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

ALABAMA

Expansion at State Medical College.—Razing the George Eaves Surgical Tuberculosis Clinic the first week in September was the first step in the development of a medical center at the Medical College of Alabama since it became a four year school under the legislation appropriating $1,000,000 for building and $366,750 annually for maintenance and operation. With a view to creating a center of medical activities, the medical college acquired by purchase two blocks and by gift one block of downtown property adjacent to the block on which the Jefferson-Hillman Hospital is located. These three blocks have been allocated to certain other institutions that either are prepared to build as affiliated units or have prospects of doing so. These activities include a University of Alabama Center of Adult Education, Jefferson County public health building, a crippled children's clinic and a veterans' hospital. The Crippled Children's Clinic is a nonprofit organization of Alabama citizens who for many years have attempted to offer orthopedic services to the indigent crippled children of the state. They started out limiting their services to Jefferson County, in which Birmingham is located, but as funds were available they extended services to the crippled children of the state. This organization has raised $1,000,000 with which to build a crippled children's hospital in the University of Alabama Medical Center in Birmingham and has already purchased a block of property on which to build. The maintenance and operation of the hospital will remain in the hands of the board of directors of the organization, but the Medical College of Alabama, Birmingham, has been granted professional control and teaching privilege in the institution. The Jefferson County public health building is to be located in the medical center and is to be erected at a cost of a little more than one-half million dollars, which has been allocated by state, county and city governments. The university medical college will enjoy close affiliation with this organization in that the director of the public health program will be chief of the department of public health in the medical college. The University of Alabama Adult Education Center, which handles the university adult education program, will be built in the medical center and the first unit is expected to go into construction late in 1946. Facilities will be provided in the structure for the training of certain auxiliary medical personnel. The veteran's hospital which is to be built in the medical center will cost a little more than $7,000,000. This will be a 500 bed hospital with living quarters for approximately fifty staff members. The land for erection of the hospital has been purchased from the University of Alabama.



Medical College and University Hospital, Birmingham, Ala.

CALIFORNIA

Changes in Health Personnel.—Dr. Kenneth W. Haworth, formerly of Pratt, Kan., was appointed health officer for Humboldt County, effective October 1.——Dr. Evelyn F. Buchheim, for the past two years district medical officer for the Fresno area, California Department of Public Health, has resigned.——Dr. Harold T. Castberg has resigned as chief of the Bureau of Adult Health to become director of field investigations for the U. S. Public Health Service, Industrial Hygiene Division, Bethesda, Md. Dr. Lester Breslow is acting chief of the bureau of adult health.

Gimbel Lectures on Sex Psychology.—The Jacob Gimbel Lectures on Sex Psychology were delivered at Stanford University School of Medicine, San Francisco, by Margaret Mead, Ph.D., associate curator of ethnology, American Museum of Natural History, New York. The individual titles of the lectures were:

Biological Determinants, November 4.
Sex Patterns in Bali and New Guinea, November 5.
Cultural Determinants, November 6.
Patterns of Sex Difference in Contemporary United States, November 7.
Sex Differentiation and Creativeness, November 8.

The lectures were established by the late Jacob Gimbel under the joint administration of the University of California and Stanford University medical schools, San Francisco.

ILLINOIS

Positions Available.—Open competitive examinations for nurses with the Illinois Department of Public Welfare will be held December 7 by the Illinois State Civil Service Commission. Applications should be filed by November 16 with the commission, 501 Armory Building. About thirty-nine nurses will be appointed to positions at state hospitals, schools and other welfare institutions. The salary range for nurse I is $1,800 to $2,400. Other examinations on call for the Illinois Department of Public Welfare include physician I, hospital attendant, laboratory technician I, x-ray technician and psychiatric social worker I.

Chicago

Dr. Ivy Honored.—On October 23 Dr. Andrew C. Ivy, vice president in charge of the Chicago Professional Colleges of the University of Illinois, was guest of honor at a banquet given by former students and associates. A feature of the occasion was the proposal by Dr. Anton J. Carlson, a teacher of Dr. Ivy at the University of Chicago, to establish the Andrew C. Ivy Student Loan Fund at Northwestern University, where Dr. Ivy had been a member of the staff for twenty years until his recent appointment at the University of Illinois (The Journal, July 13, p. 928). Dr. Carlson contributed the first check for the creation of the fund.

Information Center on Alcoholism.—Plans are under way to open an information center on alcoholism in the loop by January 1 under the auspices of the newly organized Chicago Committee on Alcoholism (The Journal, October 19, p. 399). A survey will be made among hospitals to determine whether scientific treatment can be obtained and the center will serve as a referral agency, according to the Chicago *Daily News*, October 29. Later a broad research program will be undertaken, financed by contributions from private individuals and organizations. Temporary officers of the Chicago committee are Dr. Anton J. Carlson, University of Chicago, chairman; Walter O. Cromwell, Juvenile Protective Association, vice chairman, and Alexander Rotchan, Council of Social Agencies, secretary-treasurer.

LOUISIANA

New Division of Cancer Control.—Dr. James S. May, Oberlin, has been appointed acting head of the newly organized division of cancer control in the Louisiana State Department of Health. The project will be financed by an appropriation from the U. S. Public Health Service of about $50,000. This sum cannot be expended for treatment or establishment of cancer clinics but will be employed to make a survey of the state and to promote an educational campaign against cancer.

MAINE

Executive Secretary for State Medical Association.—Mr. W. Mayo Payson, house chairman, Legal Affairs Committee in the state legislature, Portland, has been appointed executive secretary of the Maine Medical Association, a new position created by the house of delegates at its annual meeting in Poland Spring in June. The appointment was effective November 1. Mr. Payson has held the position of corporation counsel of the city of Portland for the past ten years. He was Portland representative to the Maine legislature for five consecutive two year terms and is currently house chairman of its important legal affairs committee, a member of the committee on the reference of bills in the existing legislature and chairman of a recess committee studying state pensions. He has also served as house chairman of both the legislative research and the code committee and has been a member of the judiciary and federal relations committees. He had been a practicing attorney in Portland for sixteen years when appointed by the city council in July 1936 to the corporation counsel post.

MARYLAND

Personal.—Dr. Stanley H. Macht, formerly of Crewe, Va., has been appointed associate professor of radiology at the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore.

Association of Public Health Laboratories.—The Maryland Association of Medical and Public Health Laboratories met at Goucher College, Baltimore, October 30. Among the speakers were Mr. Paul A. Rohde, associate bacteriologist, state department of health, "Laboratory Diagnosis of Infections Caused by Pyocyaneus and Friedlander's Bacilli," and Dr. Harry Eagle, adjunct professor of bacteriology, Laboratory of Experimental Therapeutics of the U. S. Public Health Service and Johns Hopkins School of Hygiene and Public Health, Baltimore, "The Use of British Antilewisite in the Treatment of Arsenic Poisoning in Animals and in Man."

MASSACHUSETTS

Students to Report Effects of Deficient Oxygen Supply.—Boston University School of Medicine is now using a decompression chamber lent by the Army Air Force for research and experimentation in medical problems at high altitudes. The chamber, formerly used at Westover Field, Chicopee, for the training of flying personnel in the use of oxygen equipment, has been set up on the campus of the university school of medicine, 80 East Concord Street, and is now being used for experiments and demonstrations illustrating the relation of oxygen to the human system and results which occur when the oxygen supply is decreased. Students are able to sight their own reactions to the study by personally experiencing physiologic effects of the deficient oxygen supply. Under the arrangement the school of medicine is under contract to report results of the experiments to the Army Air Force and to aid in teaching a section of aviation medicine, now included in the physiology section course.

MICHIGAN

Dearholt Medal Awarded.—Theodore J. Werle, executive secretary of the Michigan Tuberculosis Association, was presented with the annual Dearholt Medal at the annual banquet of the Mississippi Valley Conference on Tuberculosis in Chicago September 26. The medal is given each year for exceptionally meritorious work in the field of tuberculosis control. Mr. Werle has been executive secretary of the Michigan Tuberculosis Association for twenty-five years.

Personal.—Dr. Christopher G. Parnall, Rochester, N. Y., director of the hospital of the University of Michigan, Ann Arbor, from 1918 to 1924, has opened a hospital consultant's office in Ann Arbor.——Dr. Abraham Leenhouts, Holland, who has completed fifty years in the practice of medicine, has been appointed campus physician of Hope College.——Maurice L. Moore, Ph.D., assistant director of research, Frederick Stearns and Company Division, Sterling Drug Company, Detroit, has been elected chairman of the division of medicinal chemistry of the American Chemical Society for 1947.——Dr. Pearl E. Hackman, formerly of Reading, Pa., has been appointed school physician for Lansing.

Fellowship in Anatomy.—Dr. John D. Green, a member of the faculty of the University of Cambridge, England, is in Detroit as a recipient of the Alexander Blain Hospital Fellowship in anatomy for 1946-1947. Research in fields of neurology and neural anatomy will be directed by Dr. Green at Wayne University College of Medicine, Detroit, for one year under the terms of the fellowship. Selection of the recipient was made by a faculty committee following acceptance of the $5,000 fellowship grant from the hospital by the Detroit Board of Education. Dr. Green, who has been on the Cambridge faculty since 1943, was trained at St. John's College and the Radcliffe Infirmary at Oxford, where he was awarded the hospital prize in obstetrics. He held various clinical appointments at the Royal Infirmary, Sheffield, and was a recipient of the Hallett Prize of the Royal College of Surgeons for research in anatomy.

MINNESOTA

Meeting of Radiologists.—The Minnesota Radiological Society held a meeting in Rochester, October 26. Among the speakers were:

Dr. Samuel F. Haines, Rochester, Radioactive Iodine in the Treatment of Exophthalmic Goiter.
Dr. John J. Wells, Rochester, Unusual Case of Giant Cell Tumor of Bone Treated with X-Rays.
Dr. Robert E. Fricke, Rochester, Role of Alpha and Beta Particles in Radium Therapy.
Dr. John D. Camp, Rochester, Amebiasis in Naval Personnel.
Dr. Harry M. Weber, Rochester, A Case of Diffuse Lymphomatous Involvement of the Colon.
Dr. Howard B. Burchell, Rochester, The Clinical Syndrome Associated with Pulmonary Arteriovenous Fistula: Report of a Case.
Drs. Burchell and Oscar T. Clagett, Rochester, A Case of Pulmonary Arteriovenous Fistula (motion picture).
Dr. Byrl R. Kirklin, Rochester, The Diagnosis of Carcinoma of the Stomach by Chest Radiography.
Dr. John R. Hodgson, Rochester, Lesions of the Small Bones of the Feet: Neurotropic or Infectious?

NEBRASKA

Licenses Revoked.—The state of Nebraska recently revoked the medical licenses of Drs. James C. Anderson and Philip T. Campbell, Omaha, charged with second degree murder in the death of Marian Blyth. Copies of the revocation orders issued by Dr. Wallace S. Petty, Lincoln, director of the Nebraska Department of Health, were received by Assistant County Attorney Philip Kneifl. The orders state that from April 23 to April 26 Drs. Anderson and Campbell "engaged in immoral, unprofessional and dishonest conduct, knowingly and wilfully failed to notify the proper authorities of the death of Marian Blyth; knowingly and wilfully failed to sign a death certificate; knowingly and wilfully unlawfully disposed of the body by depositing it in the Missouri River."

NEW JERSEY

Kenneth Thompson Joins Roche-Organon.—Dr. Kenneth W. Thompson, clinical professor of surgery, Tufts College Medical School, Boston, has been appointed medical director of Roche-Organon, Inc., Nutley. Dr. Thompson was formerly managing editor of the *Journal of Clinical Endocrinology.*

NEW YORK

New Director of Cancer Research.—Joseph G. Hoffman, Ph.D., physicist, has been named director of cancer research at the Rockwell Park Memorial Institute, Buffalo.

Study of Twins.—Newspapers reported that a statewide study of twins aged 60 years and older is being carried out under the direction of Dr. Frederick MacCurdy, New York City, state commissioner of mental hygiene. The study has been undertaken by the state department of mental hygiene in its research into physiologic and psychiatric processes of aging. Information given by voluntary participants will be kept confidential.

Edward Rogers Goes to California.—Dr. Edward S. Rogers, Albany, has resigned as assistant commissioner for medical administration to become professor of public health and medical administration and dean of the recently established school of public health at the University of California, Berkeley. According to the New York *Times*, Dr. Rogers will commence his resident duties as dean with the opening of the next semester in January. During the intervening weeks he will conclude his state duties, study public health and medical care programs in the United States and Canada, and visit a number of schools of public health.

Ralph Horton Named to New Position.—Dr. Ralph Horton, Oneonta, has been appointed general director of the tuberculosis hospitals in the New York State Department of Health, it was announced October 11. Dr. Horton, now director of the Homer Folks State Tuberculosis Hospital at Oneonta, will be responsible for inspection and supervision of all county and city hospitals which will take part in the statewide program to eliminate tuberculosis in the state within twenty years. Residents of the state suffering from the disease may now enter, free of charge, county and city hospitals authorized by the state health department to receive such patients. The new state program provides for state aid to local tuberculosis hospitals to the extent of about 50 per cent of the operating costs and will increase the state's annual health expenditures by $7,000,000.

New York City

Harvey Lecture.—Dr. Arnold R. Rich, professor of pathology, Johns Hopkins University School of Medicine, Baltimore, will deliver the second Harvey Society Lecture of the current series at the New York Academy of Medicine, November 21, on "Hypersensitivity in Disease."

New Professor of Radiology.—Dr. Harold L. Temple, assistant professor in charge of teaching radiology, Cornell University Medical College, has been appointed professor of radiology. Dr. Temple, who graduated at the University of Nebraska College of Medicine, Omaha, in 1935, has been a member of the staff of Cornell since 1941.

Tumor Clinic at Harlem Hospital.—The Tumor and Cancer Prevention Clinics at Harlem Hospital were formally opened with appropriate exercises October 24. Speakers included Dr. Louis T. Wright, director of surgery, Harlem Hospital, New York City, and Dr. Edward M. Bernecker, New York City commissioner of hospitals.

Grant for Research.—The department of pharmacology of Cornell University Medical College has accepted a research grant from the Cinchona Products Institute of New York for a study of the effects of cinchona alkaloids on heart arrhythmias. The work is to be carried on under the direction of Dr. Harry Gold, using various alkaloids of high purity, especially manufactured for this study by N. V. Nederlansche Kaninefabriek, Maarssen, the Netherlands.

First Fellowship Awarded by Eye Bank.—Dr. Walter Kornbleuth, ophthalmologist of the Hebrew University in Palestine, has been announced as the recipient of the first international fellowship to be granted by the Eye Bank for Sight Restoration, New York 21. The fellowship is for postgraduate training in ophthalmology and research problems relating to the cornea under the direction and supervision of a member of the staff of the Wilmer Institute at the Johns Hopkins University School of Medicine, Baltimore.

NORTH CAROLINA

Changes in Health Personnel.—Dr. Everett H. Ellinwood, Raleigh, has been named health officer for the Catawba-Lincoln District Health Department, effective July 1, succeeding Dr. Harold C. Whims, Newton, who holds a similar position in Buncombe County.

Medical Symposium.—The Duke University School of Medicine, Durham, and Duke Hospital combined in sponsoring their ninth annual medical symposium in Durham, October 4-5. Among the speakers were:

Dr. Eugene A. Stead Jr., Atlanta, Ga., Recent Advances in the Study of the Circulation and Their Application to Clinical Problems.
Dr. Alfred Blalock, Baltimore, Surgery of the Heart and Great Vessels.
Dr. Louis K. Diamond, Boston, The Clinical Importance of the Rh Factor, Especially in Obstetrics.
Dr. Francis J. Braceland, Rochester, Minn., Some Lessons Learned from World War II.
Dr. Ralph M. Tovell, Hartford, Conn., Lessons in Anesthesiology Learned in the European Theater of Operations.
Dr. Idys Mims Gage, New Orleans, Thrombophlebitis and Phlebothrombosis.
Dr. Sumner L. S. Koch, Chicago, The Modern Treatment of Burns.
Dr. Augustus Thorndike Jr., Boston, Problems of Convalescence and Rehabilitation in General Practice.
Dr. Francis R. Dieuaide, New York, The Application to Civilian Practice of New Knowledge of Tropical Diseases.
Dr. Chester S. Keefer, Boston, Streptomycin.
Dr. Theodore J. Abernethy, Washington, D. C., Differential Diagnosis of Primary Atypical Pneumonia.
Dr. John F. Mahoney, Staten Island, N. Y., The Modern Treatment of Syphilis and Gonorrhea.
Dr. Chester M. Jones, Boston, The Therapy of Acute and Chronic Hepatitis.

OHIO

University News.—Dr. Harold C. Haynie, recently released from military service, has been appointed assistant medical director of the Ohio State University Hospital and its outpatient department and as assistant professor of medicine and hospital administration in the medical school.

Study on Metabolism of Bacteria.—A grant of $17,200 from the U. S. Navy to the department of biochemistry of Western Reserve University School of Medicine, Cleveland, for the study of the metabolism of bacteria was announced October 24. The grant will support the first year's work in a three year program to be conducted by Harland G. Wood, Ph.D., head of the department, and Lester O. Krampitz, Ph.D., and Merton F. Utter, Ph.D., associate professors of biochemistry, using bacteria as experimental organisms to throw more light on living processes in human beings. The research also will be directed toward a clearer understanding of the action of antibiotics such as penicillin, antiseptics and other chemicals on bacteria, with a view toward increasing their effectiveness. The department of biochemistry recently received a grant of $13,800 from the American Cancer Society for a research project using "tracer elements" in the study of fundamental processes of life.

PENNSYLVANIA

Philadelphia

Lectures on Mental Hygiene.—The third series of lectures on mental hygiene, arranged by the committee on nervous diseases and mental hygiene of the Philadelphia County Medical Society, opened at the society's headquarters, November 4, to continue through December 16. Among the participants:

Dr. LeRoy M. A. Maeder, November 4, Adult Maladjustment Traceable to Childhood Experiences.
Dr. Paul Sloane, November 11, Mother and Baby.
Dr. Frederick H. Allen, November 18, The Baby Becomes a Person.
Dr. Robert S. Bookhammer, November 25, Family Relationships.
Dr. Gerald H. J. Pearson, December 2, The Child Meets Reality.
Mr. E. Gillet Ketchum, December 9, The Psychologic Aspect of School Disabilities.
Dr. Margaret DeRonde, December 9, The Psychiatric Aspect of School Disabilities.
Dr. Oliver S. English, December 16, Adolescence.

TENNESSEE

Physician Aids Library.—Dr. Phocian W. Malone, Big Springs, Texas, has set up a library trust for Watertown High School, Lebanon, of $500 annually for a period of ten years to supply current library needs. Dr. Malone graduated at the Watertown High School and is now senior surgeon at the Malone-Hogan Clinic and Hospital at Big Springs, Texas.

Pathologists Organize.—The Memphis Society of Pathologists was organized October 11 with Dr. Douglas H. Sprunt, professor of pathology at the University of Tennessee College of Medicine, Memphis, as temporary chairman. Charter members of the society include:

Dr. Thomas C. Moss, Memphis, director of laboratories, St. Joseph's Hospital.
Dr. Nolan E. Leake, Memphis, pathologist, Baptist Memorial Hospital.
Dr. Isadore N. Dubin, assistant professor of pathology, University of Tennessee College of Medicine, Memphis.
Dr. Alfred Golden, Memphis, director of laboratories, Baptist Memorial Hospital.
Dr. Israel D. Michelson, professor of bacteriology, University of Tennessee College of Medicine, Memphis.
Dr. Aubrey C. Gose, pathologist, Oakville Sanatorium, Oakville.
Dr. Edwin D. Murphy, instructor in pathology, University of Tennessee College of Medicine, Memphis.
Dr. Henry D. Chipps, pathologist, Methodist Hospital, Memphis.
Dr. Randolph T. Shields, assistant professor of pathology, University of Tennessee College of Medicine, Memphis.

WASHINGTON

State Organization for Spastic Children.—The Washington Spastic Children's Society, organized May 25 on a statewide basis, is active in presenting a bill to the legislature which meets next January to assist in effecting its objectives. The society plans to establish hospital or boarding schools, tentatively set at one in Seattle and one in Spokane and to have day schools in some twelve to fifteen cities throughout the state. What is described as a new feature is the establishment of an industrial school for the group by spastic children with somewhat lower mentality, the type which cannot get along well in any type of school and has sufficient mentality to carry out certain activities. Officers of the group include Merrill W. Boyack, Seattle, president; M. L. Graybill, Spokane, vice president; Phyllis M. Corrison, secretary; Helmer Kastner, treasurer, and Dr. Hulett J. Wyckoff, Seattle, medical adviser.

WEST VIRGINIA

Personal.—Dr. Olan T. Coffield, Morgantown, has joined the staff of the University Health Service at West Virginia University, of which Dr. John J. Lawless is director. Dr. Coffield received his A.B. degree in 1940 and his B.S. in 1942 at West Virginia University, graduating at the University of Louisville School of Medicine in 1943. After serving his internship at Wheeling General Hospital, he was commissioned in 1944 in the Army Medical Corps, serving until his release in 1946.

New Chief of Medical Services.—Dr. Harold H. Kuhn, Charleston, has been named chief of the division of medical services of the department of public assistance by Mr. Robert F. Roth, director. He will serve on a part time basis, effective November 1. There has been a vacancy in the position of chief of the division of medical services since Dr. Paul R. Gerhardt, Van, resigned in 1945 to accept appointment as director of the division of cancer control. Mrs. Mae W. Stratton, who has been acting chief of the division for several months, will serve as administrative assistant to the new director.

GENERAL

Cancer Service.—Dr. James R. Miller, Hartford, president-elect of the Connecticut State Medical Society, has accepted the chairmanship of the Service Committee of the American Cancer Committee. Other members are Dr. Robert R. Newell, Stanford, Calif.; Dr. Leonard W. Larson, Bismarck, N. D.; Dr. William W. Haggart, Denver; Dr. Alton Ochsner, New Orleans; Dr. Augusta Webster, Chicago; Dr. Bowman C. Crowell, Chicago; Dr. Alphonse R. Dochez, New York; Dr. Edward W. Chamberlain, Philadelphia; Dr. Thomas A. McGoldrick, Brooklyn; Dr. Louis H. Bauer, New York, and Dr. Edward J. McCormick, Toledo, Ohio.

Harry M. Weaver Named Director of Research.—Harry M. Weaver, Ph.D., acting director of research for the National Foundation for Infantile Paralysis, New York, has been named director of research. Previously on the faculty of Wayne University College of Medicine, Detroit, Dr. Weaver joined the National Foundation staff last February as assistant to the medical director. Dr. Weaver will be responsible for the research program of the national foundation, through which grants are made to established research organizations such as universities, public health laboratories and hospitals to enable scientific investigators throughout the country to carry on programs of research designed to find ways to prevent or cure poliomyelitis. Until the end of May this year the national foundation had authorized March of Dimes funds expenditures of $17,329,189.01 for research, education and epidemic aid in poliomyelitis. Of this amount $5,745,977.88 was authorized for support of research.

Cancer Conference.—The National Advisory Cancer Council will sponsor a conference on gastric cancer at Billings Memorial Hospital, University of Chicago, December 5-6. The conference was arranged by the Gastric Cancer Committee of the council and is the third of its kind. The first was held in 1940 in the National Cancer Institute of the National Institute of Health. The council is placing particular stress on cancer of the gastrointestinal tract, which accounts for 45 per cent of the total cancer deaths in this country. Included among the speakers will be:

Leonell C. Strong, Ph.D., New Haven, Further Observations on the Genetic Nature of Gastric Cancer in Mice.
Dr. Shields Warren and Dr. Elsie M. McPeak, Boston, Studies on the Pathology of Gastric Carcinoma in Mice.
Clarence C. Lushbaugh, Ph.D., Chicago, Experimental Hypertrophic Gastritis and Gastric Polyposis in Monkeys.
Dr. Edward B. Benedict, Boston, Observations on the Gastric Mucosa in Pernicious Anemia After Liver Therapy.
Drs. Leo G. Rigler, Minneapolis, and Henry S. Kaplan, New Haven, Pernicious Anemia and Carcinoma of the Stomach.
Dr. Cornelius P. Rhoads, New York, Highlights of Metabolism Studies in Gastric Cancer.
Dr. George T. Pack, New York, The Extension of Radical Surgery in the Treatment of Gastric Cancer.
Dr. Andrew C. Ivy, Chicago, Effect of Methylcholanthrene Orally in the Rabbit.
Dr. Leon Schiff, Cincinnati, Gastric Secretion of Radioactive Iodide in Both Health and Gastric Disease.
Dr. Alexander Brunschwig, Chicago, Concentration of Quinine in Gastrointestinal Cancers.
Drs. George N. Papanicolaou and William A. Cooper, New York, The Cytology of the Gastric Fluid in the Diagnosis of Carcinoma of the Stomach.
Dr. Franklin Hollander, New York, Experimental Exhaustion of the Gastric Mucous Barrier in Dogs and a New Technic for Studying the Cytology of Gastric Aspirates in Man.
Dr. Mandred W. Comfort, Rochester, Minn., Gastric Acidity Before and After the Development of Carcinoma of the Stomach.
Dr. Morris E. Dailey, Los Angeles, The Role of Cancer Prevention Clinics in the Detection of Early Gastric Cancer.
Drs. David State and Owen H. Wangensteen, Minneapolis, Studies of Precursor Groups of Gastric Cancer.
Dr. Frederic E. Templeton, Seattle, X-Ray Diagnosis of Early Gastric Lesions.
Dr. Marie Ortmayer, Chicago, Biologic Characteristics of Asymptomatic, Nonpalpable Tumors of the Rectum and Comparison with the Stomach.

Participating in the general discussion will be Drs. P. R. Peacock, Glasgow Royal Cancer Hospital, and Walter L. Palmer, University of Chicago.

Istanbul Hospital Seeks Surgeon.—The American Hospital of Istanbul, now renamed the Admiral Bristol Hospital, is looking for a young American surgeon skilled in surgery of the chest. The Ministry of Public Health of the Turkish republic has agreed to give the American physician appointed a five year contract, renewable at the end of five years, to serve as a government expert, his specific task being to organize and supervise the chest surgery service in the Haydar Pasha contagious diseases hospital in Istanbul, where there are 80 beds for pulmonary tuberculosis. He is to give two or three mornings a week to this work, for which he will receive from the Turkish government a nominal salary of Ltqs. 100 a month; the remainder of his time will be devoted to the Admiral Bristol Hospital. In case a suitable candidate is found, the hospital is prepared to engage him on a full time basis. The exact amount of salary is impossible to fix at the present time owing to abnormal living costs in Istanbul. However, the salary paid would be adequate to cover his traveling expenses, his living costs on a comfortable basis in this city and insurance or annuity payments in the states sufficient to guarantee him adequate retirement income. The correspondence incident to this position was sent to THE JOURNAL by the Department of State, Washington, D. C. Dr. Lorrin A. Shepard has been American director of the Admiral Bristol Hospital since 1927.

Proposed Changes for Red Cross.—Fundamental changes in the organization structure of the American Red Cross were adopted by the present governing body, the Central Committee, at its September meeting in Washington. The changes were recommended by a nationally representative advisory committee appointed last March by Basil O'Connor, national chairman, to study the organization of the Red Cross in the light of the tremendous growth in its membership and services to the people since 1905, when its present congressional charter was granted. Announcing the action at the recent meeting after transmitting the recommendations to the chapters, Mr. O'Connor said they are of greatest significance to the Red Cross organization at all levels. The recommended revisions to the charter of the organization, unchanged since 1905, provide at the national level for greatly increased representation from the chapters and from the public at large on the national governing body and provide at the chapter level for participation by the membership in all chapter operations. Most significant changes include:

Expansion of the present governing board from eighteen members to fifty members, thirty of whom would be drawn from local chapters under a system of nomination and election and twelve of whom would be elected to represent the national interests at large.

A system of regular rotation in office of the governing bodies in chapters as well as in the national organization.

Discontinuance of the Board of Incorporators provided for in the 1905 charter.

A provision enabling any twenty-five members to appeal to the national organization basic grievances as to matters of chapter procedures.

A provision allowing the establishment of committees chosen by the chapters within each state for the purpose of liaison with state relief, health and welfare agencies.

A new system of auditing separately all accounts of local chapters as well as of the national organization.

Elimination of present classification of memberships according to sums contributed.

At present the Central Committee or governing board of the Red Cross consists of eighteen persons. Six are chosen by chapter delegates, six appointed by the President of the United States and six named by the Board of Incorporators, a body of sixty-five persons initially named in 1905 for the purpose of bringing the corporate organization into being. The incorporators have elected their own successors since that time. The President of the United States appoints the national chairman as well as five other members to the Central Committee from the Departments of State, War, Navy, Treasury and Justice. Under the proposed changes, the Central Committee would be increased to fifty members and its name changed to the Board of Governors. Of the fifty members, thirty would be elected by delegates of the chapters at the national convention held each year, twelve would be elected by the Board of Governors itself as members-at-large, and eight would be selected by the President of the United States, of whom one would be designated by him as president of the Red Cross. Among those selected by the President of the United States from government departments and agencies, at least one and not more than three would be chosen from the armed forces. The election of the governors by the chapters at the national conventions would be under procedure insuring geographic distribution as well as representation of chapters of all sizes.

CORRECTION

Typhoid Deaths.—In the list of deaths from typhoid published in THE JOURNAL July 6 the statement was made that Omaha, although in the first rank, had a typhoid death rate of 0.4 per hundred thousand of population. Information has now been received indicating that the report from Omaha was in error and that there were no deaths from typhoid in Omaha during the year covered by the tabulation.

Deaths

Alfred Iverson Folsom ⊕ Dallas; Southwestern University Medical College, Dallas, in 1908; born in McGregor, Texas, May 9, 1883; carried on postgraduate work at the Mayo Clinic, Rochester, Minn.; joined the staff of Baylor University College of Medicine, Dallas, in 1921, serving as professor from 1923 to 1943, when he accepted a similar position at the then new Southwestern Medical College; vice chairman of the medical board of Baylor University Hospital, created in 1946 to supervise teaching program; chief of the department of urology, Parkland Hospital, Dallas, since 1923; honorary professor of urology, University of Guadalajara, Guadalajara, Jalisco, Mexico; fellow of the American College of Surgeons and a specialist certified by the American Board of Urology; member of the Texas Surgical Society and the South Central Urological Association, having been president of both, the Dallas County Medical Association, the Texas State Medical Association and the Dallas Southern Clinical Society; chairman of the Section on Urology, American Medical Association, in 1931 and member of its House of Delegates in 1933; president of the American Urological Association at the time of his death, October 3, aged 63, which resulted from an automobile collision.

Daniel Cleveland Patterson ⊕ Bridgeport, Conn.; College of Physicians and Surgeons, Baltimore, 1906; born in New Brunswick, Canada, Oct. 1, 1882; member and past president of the state board of medical examiners, Connecticut State Medical Society and the New England Surgical Society; member of the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; an officer in the medical corps of the U. S. Army, serving overseas during World War I; on the staff of the Bridgeport Hospital; died September 12, aged 63, of massive subarachnoid hemorrhage and coronary arteriosclerosis.

Thomas Almy ⊕ Fall River, Mass.; Harvard Medical School, Boston, 1909; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member of the New England Obstetrical and Gynecological Society, of which he had been vice president and president, and the New England Pediatric Society; served on the staffs of the Union and Fall River General hospitals; died September 6, aged 63, of arteriosclerosis.

Charles Marion Anderson, Huntington, W. Va.; University of Louisville (Ky.) Medical Department, 1894; died September 4, aged 80, of senility and uremia.

Sanford Milton Blunk ⊕ Virden, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1911; served as member and president of the Virden Community High School Board; died in St. John's Hospital, Springfield, September 8, aged 68, of metastatic carcinoma following chronic exposure to x-ray radiation to hand.

Albert Charles Carter, Pensacola, Fla.; Vanderbilt University School of Medicine, Nashville, 1910; member of the American Medical Association; on the staff of Pensacola Hospital; died September 1, aged 59, of coronary thrombosis.

Cline M. Chipman ⊕ Washington, D. C.; George Washington University School of Medicine, Washington, 1907; associate in anesthesia at his alma mater; member of the American Society of Anesthetists; on the staffs of the George Washington University, Emergency and Gallinger hospitals; found dead September 7, aged 62.

Frank S. Davidson, Chicago; Rush Medical College, Chicago, 1897; member of the American Medical Association; formerly on the staffs of the Ravenswood and Alexian Brothers' hospitals; died September 27, aged 71, of cardiovascular renal disease.

Homer Willard Davis, Alton, Ill.; Washington University School of Medicine, St. Louis, 1900; member of the American Medical Association; fellow of the American College of Surgeons; chief of surgery at the Alton Memorial Hospital and surgical consultant to St. Joseph's Hospital; died September 5, aged 72, of carcinoma of the liver.

James William Davis, Ozark, Ark. (licensed in Arkansas in 1903); died September 12, aged 78, of strangulation of a loop of bowel by Meckel's diverticulum.

William Eugene Delaney Jr., ⊕ Williamsport, Pa.; Jefferson Medical College of Philadelphia, 1923; fellow of the American College of Surgeons; on the staff of the Williamsport Hospital, where he died September 11, aged 52, of cirrhosis of the liver and duodenal ulcers.

Frank Gerald Douglass ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; on the staffs of the Englewood and St. George hospitals; died September 11, aged 60, of chronic myocarditis.

George Lefferts Fox ⊕ Hartford, Conn.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1924; formerly director of health education at Hartford Public High School; served on the faculty of the University of Connecticut in Storrs; at one time affiliated with the Lamont Infirmary, Exeter Academy, Exeter, N. H.; member of the New Hampshire Medical Society; died in the Hartford Hospital September 1, aged 59, of coronary thrombosis.

Frederic Michael Groner, Yorkville, Ill.; Loyola University School of Medicine, Chicago, 1921; for many years county coroner; on the staff of St. Joseph Mercy Hospital in Aurora; died September 9, aged 63, of chronic endocarditis.

John Alexander Hembree, Pearson, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1905; member of the American Medical Association; formerly an officer in the Civilian Conservation Corps; at one time served as a captain in the medical reserve corps of the U. S. Army, stationed at Camp Shelby, Miss.; major in the medical reserve corps of the U. S. Army, not on active duty; died September 15, aged 67, of heart disease.

Mordecai Laughlin Howard, Danville, Ill.; Pulte Medical College, Homeopathic, Cincinnati, 1891; member of the American Medical Association; on the staff of the Lake View Hospital, where he died September 16, aged 79, of carcinomatosis.

Irvin F. Hummon ⊕ Oak Park, Ill.; Chicago College of Medicine and Surgery, 1917; died September 26, aged 72, of coronary occlusion and arteriosclerosis.

Lee F. Hunt ⊕ Anderson, Ind.; Kentucky University Medical Department, Louisville, 1903; formerly secretary of the Madison County Medical Society; an officer in the medical corps of the U. S. Army, serving overseas during World War I; affiliated with the St. John's Hickey Memorial Hospital, serving at one time as president of the staff; died September 9, aged 69, of massive retroperitoneal hemorrhage and dissecting abdominal aneurysm.

Joseph Bolton Knipe, Sparkill, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1903; served during World War I; died September 4, aged 75, of heart disease.

John Liebau ⊕ Chicago; Bennett Medical College, Chicago, 1914; died September 24, aged 76, of coronary thrombosis.

Hermann Robert Markt, Wingdale, N. Y.; Schlesische-Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau, Prussia, Germany, 1923; affiliated with the Harlem Valley State Hospital; died July 4, aged 45, of coronary thrombosis.

Eugene Augustus Meacham ⊕ South Amboy, N. J.; New York University Medical College, New York, 1898; medical examiner for the Middlesex County Draft Board during World War I; affiliated with Roosevelt Hospital in Metuchen and the South Amboy Memorial Hospital; died September 24, aged 73, of endocarditis.

John Ray Newcomb ⊕ Indianapolis; Medical College of Indiana, Indianapolis, 1904; served during World War I; chairman of the Marion County Procurement and Assignment Service during World War II; colonel, medical reserve corps, U. S. Army, not on active duty; died in the Methodist Hospital September 3, aged 66, of myocardial failure.

Adolph Benedict Schneider ⊕ Cleveland; Cleveland Medical College, 1894; on the staff of the Huron Road Hospital in East Cleveland; at one time professor of medicine and physical diagnosis at the Cleveland Homeopathic Medical College; died in the Memorial Hospital, North Conway, N. H., September 3, aged 79, of injuries received in an automobile accident.

Barney Dunbar Sibley, Birmingham, Ala.; Birmingham Medical College, 1898; member of the American Medical Association; formerly health officer of Warrior; died in St. Vincent's Hospital September 5, aged 75, of cerebral hemorrhage and cardiovascular renal disease.

Ernest Carlton Wood, Bloomfield, Ky.; Kentucky University Medical Department, Louisville, 1906; member of the American Medical Association; died August 15, aged 68, of cerebral hemorrhage.

Irving Zahler, St. Petersburg, Fla.; Long Island College Hospital, Brooklyn, 1918; died August 15, aged 51, of pulmonary edema.

Test of the Sensitivity of Bacteria to Penicillin and Sulfonamides

At a recent meeting of the Academy of Medicine Lecocq and Chauchard (noted for his studies on chronaxia) and Mrs. H. Mazoue presented a new method for determining the penicillin and sulfonamide sensitivity of bacteria. The authors made studies on the white rat, by oral or parenteral routes, the penicillin and the "para-aminophenyl sulfonamide" : 1.162 F. They found an increase of the nervous chronaxia and a diminution of the muscular chronaxia. The consecutive ingestion of two drops of a suspension of bacteria (corresponding to 500 million organisms) treated with formaldehyde and heated at 149 F. produced the following effects: The resisting bacterium inhibits the disturbances and brings the chronaxia back almost to normal, the sensitive bacteria leave it as altered by penicillin and sulfonamides. The authors think that the exotoxins or endotoxins with which the resisting bacteria are endowed hinder in vivo the action of penicillin and sulfonamides on the neuromuscular system. This test shows the sensitivity or the resistance of bacteria to penicillin and sulfonamides by a series of chronaximetric readings made within the twenty minutes following the ingestion or the injection of these products made after a previous ingestion of bacteria treated with formaldehyde and heated.

Congress of French Speaking Electroradiologists

The Congress of French Speaking Electroradiologists took place in Paris from the 9th to the 12th of October. Among others, important Swiss, Dutch and Belgian delegations were present. Baudouin and Fischgold read papers on the development and prospects of clinical electroencephalography. Lachapelle of Bordeaux reported on chronic vertebral rheumatism. Lamarque and Gros of Montpellier reported experiments on contact radiotherapy in rectal cancers. In case of nonstenotic cancer the authors use tubes of the Philip type, the direction of the beam being in the axis of the tubes. The three weeks course comprises two weekly treatments, each consisting of 2,500 roentgens. In 50 cases (31 not extirpable and 19 inoperable, mostly on account of the general condition) there have been 6 deaths, 12 apparent recoveries (4 of which date back from thirteen to seventeen months) and 12 improvements; in 16 patients the course of treatment is not yet finished. The authors have seen 4 cases of cylindric epithelioma regressing rapidly and completely; in a few months the surface of the mucosa becomes normal again. The authors emphasize that it is too soon to appreciate the absolute efficacy of this treatment, but Chaoul's statistics (Germany) covering a much longer period confirm this success. These statistics, published in 1943, show 62 recoveries among 104 cases treated from two to eight years previously.

Cottenot and Bourdon reported results obtained from December 1942 to January 1945 at the St. Louis Hospital by contact radiotherapy on 473 patients showing 761 dermatologic disorders. In 113 cases of epithelioma of the face they had 90 per cent recoveries together with 70 per cent of esthetic cicatrization and this after a lapse of one to three years. The most interesting results were obtained on cancers of the commissure of the lips, of the eyelids, of the nose and of the pinna. Sixteen patients were nonsterilizable. In 21 cases of angioma of children under 2 years there were 15 very good results, 2 good and 3 moderately good. Of 15 keloid cicatrices there were 11 very good and 4 good results. The treatment of 500 warts, especially plantar warts, has given quick results. It is the rapidity of the treatment of benign cutaneous disorders that the author emphasizes.

Inauguration of the Royal Institute of Cardiology

The inauguration of the Institute of Cardiology took place on June 15-16 under the presidency of Professor Gallavardin in the presence of its founder, Professor Laubry, a member of the institute, and of Professors Donzelot, Lian, Hermann and Giraud and of numerous representatives of the medical profession of France, Belgium, Canada, Greece, Lebanon and Mexico. The creation of this center of research was considered by Professor Laubry in 1938 but was delayed by the war and the Nazi occupation; thanks to the activity of its promoters, it has been realized after the liberation. Laboratories of physiology provided with the newest apparatus and a modern hospital are at the disposal of Professor Jourdan, scientific director of the institute.

New Dean of Paris Faculty of Medicine

Professor Baudouin having retired, the Paris Faculty of Medicine has elected as dean for five years Professor Leon Binet. He has been titular chairman of the department of physiology of the Paris Faculty of Medicine since 1930 and a member of the Academy of Medicine since 1939. He had also been a member of the institute since 1942.

AMSTERDAM, Oct. 26, 1946.

Camp Vertigo

In an article published in the *Nederlandsch tijdschrift voor geneeskunde* **90:**1000, 1946 Dr. J. Kuilman has reported his experience with 412 cases diagnosed in war prisoners in Batavia during 1944 and 1945. The patients complained of vertigo of one to fifteen minutes' duration from once or twice a week to several times a day. The recumbent position did not prevent it, but sudden movements or turning the head to one side resulted in heavier types of attack accompanied with nausea and vomiting. Headache and uncertainty of gait was experienced in the intervals. On turning the eyes laterally one noticed nystagmus, which persisted as long as one kept looking to that side. During nystagmus there were attacks of vertigo and nausea. There was a tendency to fall to the side to which the eyes were turned. Labyrinthine and lateral nystagmus interfered with each other in the sense of homolateral synergism or contralateral antagonism. Patients sitting inside a vertically black and white striped rotating cylinder exhibited the phenomenon of optic nystagmus, which in its turn interfered with the lateral nystagmus much as the labyrinthine nystagmus did. Vertigo, nausea and falling to one side were frequent in this experiment in patients with camp vertigo. Of the patients with these complaints, 37 were "camp deaf". They were deaf for low tones, whereas distant deafness was less. The deafness was not vestibular. Many of these patients with camp vertigo have suffered from intestinal trouble and malnutrition and they had burning feet, camp eyes, pellagra, beriberi and digestive disorders. These additional conditions confirmed the impression of a deficiency disease resulting in a disorder of the supranuclear mechanisms that are concerned with the coordination of eye movements and equilibrium. There was no indication of peripheral vestibular damage. It is suggested that deficiency of B_2 vitamins would underlie the condition of mainly neurologic character. Yeast gave benefit as long as it was available.

Nicotinic acid amide gave some improvement. (It came from a supply of the American Red Cross in 1945.) Yeast treatment was found most efficient of all, and it had to be continued for months before all the symptoms disappeared.

Prostatism Coincident with Periurethral Adenoma

In a dissertation presented to Leiden University Dr. J. Glazenburg stated that treating male mice with estrogens results in a considerable increase in the weight of the bladder and in hypertrophy of the two smooth muscle sphincters and of the external striated sphincter. Metaplastic changes in the coagulating gland are reminiscent of those found in the human periurethral glands, but owing to the difference in topography a mechanical obstruction to micturition cannot be inferred from this condition. Testosterone counteracts the morphologic and functional effects of estrogens, at least partially. The experimental technic consisted in measurements of opening and closing pressure of the sphincter system and in that of the rapidity of outflow. Anesthetics reduce an increased resistance; therefore a reflex mechanism must be assumed. Results obtained with curare and papaverine show that the external sphincter, though hypertrophic, does not materially contribute to the resistance of emptying. Experiments with atropine and ergotamine show that both cholinergic and adrenergic stimuli account for the resistance opposed to micturition by the internal sphincter. A disturbance of coordination between the smooth muscle sphincter and the detrusor systems accounts for the artificial prostatism of the mouse and probably for that condition in man. The functional disturbance fully accounts for difficult starting, inhibited flow and incomplete emptying of the bladder. Incoordination between sphincter and detrusor leads to functional hypertrophy of the latter. The loop of Heiss (Wesson), though included in the internal sphincter, forms an integral part of the detrusor and it hypertrophies along with the latter, thereby adding to the resistance to emptying. These are the cholinergic components of the system. To the detrusor hypertrophy a concomitant hypertrophy of the adrenergic part of the sphincter is incidental. From such a vicious circle in the functional sphere results the retention syndrome characterized by occasional sudden complete obstruction, whereas a catheter still passes without significant resistance. This whole functional disturbance is claimed to be incidental to periurethral adenoma ("prostatic hypertrophy"), which in its turn has been claimed by previous authors to originate from an endocrine imbalance. There are obvious pathologic and therapeutic implications in this concept.

Electron Microscope

In the town of Delft, where almost three hundred years ago Anthony van Leeuwenhoek made his epochal microscopic observations, an electron microscope was constructed by Mr. J. B. Le Poole. After preliminary attempts a new model of this instrument was completed in 1943. It is pointed out that the features of improvement in comparison with existing models consist of three instead of two "lenses" guiding the beam of electrons and such simplifications as are likely to reduce the cost of the instrument. The work was done in the Laboratories for Technical Physics in the Technical High School of Delft.

Personal

Professor H. Berkelbach van der Sprenkel has been appointed to the chair of histology at Utrecht University made vacant by the retirement of Professor J. Boeke.

At the University of Groningen Professor J. L. B. Engelhard retired from the chair of obstetrics and gynecology, to which Professor R. Remmelts was appointed. Professor H. M. Dekking was appointed to the chair of ophthalmology.

Field Marshal Jan Christiaan Smuts, president of the Union of South Africa, who visited this country October 10-12, was granted the degree of doctor honoris causa in jurisprudence by Leiden University.

The death was announced of Professor A. Klein, emeritus hygienist and pharmacologist of the University of Groningen. He became professor in 1907; during the war he was deported by the occupants to camps for Jews, but he survived to reach the age of 80.

Miscellaneous

At a national congress on health at Amsterdam the problem of rehabilitation of those mutilated in the war was discussed. Twelve hundred people are waiting for protheses to replace lost arms and legs. It was pointed out that provision of these prostheses is urgent both for psychologic and for utilitarian reasons.

At a meeting of the Society of Physicists at Amsterdam attended by forty foreign deputies, the discovery of the Zeeman effect was commemorated. Professor Zeeman in 1896 at the age of 30 discovered the influence of a strong magnetic field on the spectrum of radiation emitted by glowing sodium. He concluded that the phenomenon must be due to negatively charged corpuscles with a mass more than 1,800 times smaller than that of a hydrogen atom. This discovery, for which in 1912 the Nobel prize was awarded to Zeeman and Lorentz, had fundamental importance for subsequent investigations on atomic structure, such as those of N. Bohr and of Schrödinger. The ultimate results of these researches are theories on which the exploitation of atomic energy is based.

BRAZIL

(From Our Regular Correspondent)

São Paulo, Oct. 8, 1946.

Cancer of the Right Colon

Dr. Eurico da Silva Bastos says that although there is no anatomic boundary between the right and the left colon these distinctions are based on the physiopathology, symptomatology and therapeutics of conditions affecting the colon.

An increase in the number of cases of cancer of the colon and an increase in the operability with a simultaneous decrease in the mortality of the operative cases are shown by the statistics. Operations are performed in some 75 per cent of cases diagnosed. The operations are more radical and less dangerous now that we have better preparation and more adequate anesthesia.

Dr. Bastos had 2 survivors one year and two years and a half after the operation.

Dr. Eurico Bastos has observed 9 cases. Two thirds of the malignant lesions of the colon localize to the left and one third to the right.

Functional disturbances in diarrhea or constipation are rare. The presence of visible blood in the stools, which appears in 97.7 per cent of cases of cancer of the rectum and in 46 per cent of cancer of the left colon, appears in only 9 per cent of cases here. Search for occult blood in the stools, repeated x-rays and hematologic examination should be done.

Recently Coller, Kay and McIntyre found 62.5 per cent of metastases for cancer of the right colon and 60 per cent for cancer of the left colon, which would be in agreement with more complete drainage in the cecum than in the descending colon.

Dr. Eurico da Silva Bastos thinks that it justifies right colectomy with terminolateral anastomosis of the ileum to the transverse colon and extensive resection of the colonic segment where it localizes the tumor and of the tissues having blood vascular and lymphatic retia.

Correspondence

IMMUNIZATION AGAINST TETANUS

To the Editor:—I noticed in Queries and Minor Notes in THE JOURNAL, October 5, the following response to a query: "In actual practice the dose of antitoxin for prophylactic purposes has ranged from 1,500 to 20,000 units. In order to avoid confusion and to cover most exigencies, a routine dose of 10,000 American units is indicated as a substitute for the 1,500 units commonly employed. Doses of 20,000 units are justified in the presence of either severe injuries or significant delay in seroprophylaxis. When doses of 20,000 units or more are employed, it is not necessary to make additional injections for any given injury."

I am convinced that the only way in which to discontinue the use of 1,500 units for prophylaxis is the removal of this package from circulation. As long as the various biologic houses distribute these packages they will continue to be used. As long as emergency rooms of hospitals use 1,500 units the physicians will inject this dose and will continue to do so in private practice. As long as teachers in medical schools preach the time dishonored dignity of the 1,500 unit dose, medical students will use the wrong dose as externs, interns and practicing physicians. As long as various agencies, such as state boards of health, distribute the 1,500 unit package, this amount will enjoy popular approval. Sad to relate, packages of 1,500 units are used almost universally for prophylaxis. In fact, the armed forces of the United States have sanctioned the routine use of this dose. This practice continues despite the accumulation of a not inconsiderable literature which describes the occurrence of tetanus despite timely prophylaxis with the customary amounts of antitetanic serum.

I am particularly interested in this problem because of a recent sad experience. A physician saw a girl aged 2 years with a severe burn of her right leg. In addition to treatment of the burn, the child received 1,500 units of antitetanic serum. Nevertheless hyperacute tetanus supervened six days later and the child died after several days despite the most intensive specific and nonspecific treatment. The pharmacist in our local hospital lost his nephew some years ago despite the administration of 1,500 units of antitetanic serum the same day the child sustained a powder burn from a toy pistol. The signs of tetanus appeared six days after the injury, and the child died on the third day of the disease despite intensive serum treatment. The late Dr. Bernard Fantus told me that one of his nephews developed tetanus of moderate severity despite the injection of 1,500 units promptly after injury. The boy recovered in response to general care and intensive serotherapy. E. J. Radley Smith (*Proc. Roy. Soc. Med.* **35**:340 [March] 1942) has reported six failures in serum prophylaxis in a London sector during two years of World War II. Four of the 6 patients developed severe generalized forms of the disease, and 2 of these died despite intensive active treatment. Moreover, in only 1 instance was the incubation period significantly prolonged. Likewise, local tetanus appeared in but 1 patient.

It is to be emphasized that antitetanic serum is a useful prophylactic agent. Its value was demonstrated in World War I, and ample animal experiments have established its unquestionable value. To be of value, antitetanic serum must be potent. Inadequately refrigerated material and material which has deteriorated from other causes must be avoided. It must be injected promptly, or within a day or so, after injury. But, above all, the dose must be adequate.

Passive immunity is a passing (transitory) immunity. Nevertheless the duration of passive immunity may be significantly prolonged by use of the proper dose of antitetanic serum. Thus, 1,500 units confer titrable immunity for two to three weeks, 10,000 units for six to ten weeks and 100,000 units for eight to eleven weeks (Spaeth, Ralph: Serum Therapy of Tetanus, *Am. J. Dis. Child.* **61**:1146 [June] 1941. Cooke, J. V., and Jones, F. G.: The Duration of Passive Tetanus Immunity, THE JOURNAL, April 10, 1943, p. 1201). Hence I feel that, as recommended in the answer to the query, packages of 10,000 to 20,000 units should be used routinely for prophylaxis. However, it is important to emphasize that passive immunity, conferred by antitetanic serum, should be supplemented later by the properly timed inoculation of tetanus toxoid, either alone or combined with other antigens. The customary dosage schedule of tetanus toxoid should be employed. However, the time of its administration should be determined by the dose of antitetanic serum injected. This procedure is justified in terms of the principle that passive immunity interferes quantitatively with the development of active immunity. If one waits six weeks after the injection of 10,000 to 20,000 units there should be a satisfactory response to tetanus toxoid. The simultaneous use of antitetanic serum and tetanus toxoid is not an acceptable procedure. In the event of a later injury considered likely to lead to the development of tetanus, a small booster dose of tetanus toxoid, such as 0.1 cc. of fluid or alum precipitated material (McBryde, Angus, and Poston, M. A.: *J. Pediat.* **28**:692 [June] 1946) will induce antitoxic titers of adequate level and duration. The tetanus toxoid may be injected without performing sensitivity tests, because allergic reactions to tetanus toxoid are extremely uncommon. This statement does not apply to antitetanic serum, which sometimes causes serious allergic responses in previously sensitized persons.

It might be illuminating to invite further discussion of this problem to improve the present dolorous situation.

MEDICOLEGAL ABSTRACTS

Trade Mark: Use of Red Cross Symbol by Private Manufacturer.—The Federal Trade Commission entered an order prohibiting the defendant from using the words "Red Cross" or displaying the mark of the Greek red cross on, or in connection with the sale of, its products. This order was modified by the court of appeals, and the Federal Trade Commission appealed to the United States Supreme Court.

The defendant manufactures and sells a brand of toilet tissue and paper towels in interstate commerce, on each package or roll of which are a Greek red cross and the words "Red Cross." The defendant has registered the words "Red Cross" and the red cross symbol as a trade mark and featured them in its advertisements and on its letterheads. By section 4 of the American Red Cross act of 1905 it was made unlawful "for any person or corporation, other than the Red Cross of America, not now lawfully entitled to use the sign of the Red Cross, hereafter to use such sign or any insignia colored in imitation thereof for the purposes of trade or as an advertisement to induce the sale of any article whatsoever." This section was amended in 1910 so as to make unlawful the use of the Greek red cross on a white ground or the words "Red Cross" for the purpose of trade or as an advertisement "to induce the sale of any article" or "for any business or charitable purpose" by any person other than the American National Red Cross or its duly authorized employees and agents or the sanitary and hospital authorities of the army and navy. It contains, however, a provision which reads as follows:

> That no person, corporation or association that actually used or whose assignor actually used the said emblem, sign, insignia or words for any lawful purpose prior to January fifth, nineteen hundred and five, shall be deemed forbidden by this act to continue the use thereof for the same purpose and for the same class of goods,

The defendant's use of the trade name and emblem antedated Jan. 5, 1905, but in 1942 the plaintiff charged the defendant with a violation of the Federal Trade Commission act which makes unlawful "unfair methods of competition in commerce, and unfair or deceptive acts or practices in commerce." At a hearing before the commission, the commission found that

> the use by respondent [defendant] of the words "Red Cross" and of the mark of the Greek red cross to designate its products has the tendency and capacity to mislead and deceive a substantial portion of the purchasing public, in that such name and mark represent or imply that respondent's [defendant's] products are sponsored, endorsed or approved by the Red Cross; that the Red Cross is financially interested in the sale of the products; that the products are used by the Red Cross; that the products are manufactured in accordance with sanitary standards set up by the Red Cross; or that there is some other connection between the products and the Red Cross. Not only are these, in the opinion of the Commission, reasonable inferences to be drawn from the use of the name and mark, but the record affirmatively shows that the name and mark are in fact so understood and interpreted by many members of the public.

The commission also found that statements on defendant's products that they are made by defendant and that the name and mark are registered "do not serve to correct the erroneous and misleading impression created through the use of the trade name and mark." Accordingly the commission entered an order which, among other things, forbade defendant from using the words "Red Cross" to describe its products and from displaying the Greek red cross on them. On appeal to the circuit court of appeals, this order was reversed, it being held that the order went beyond permissible limits in forbidding any use of the words and the mark. The court of appeals remanded the case to the commission for the formulation of a new order which, though not forbidding the use of the words and the symbol, might require statements which would avoid any inference that the goods were sponsored or approved or in any way connected with the American National Red Cross.

There is no suggestion that the pre-1905 use of the words and the symbol was an unlawful one. It is argued, however, that although the earlier use may have been lawful, it cannot survive a finding by the commission that the use constitutes an unfair or deceptive act or practice in commerce. It is pointed out that the 1938 amendment to the Federal Trade Commission act gave the commission power to protect consumers, as well as competitors, against unfair or deceptive practices, that there are no exceptions to that broad power and that none should be implied from the Red Cross act of 1910, which, plaintiff contends, confers no general rights but only a limited immunity and should not be construed as exempting pre-1905 users of the name and emblem from regulatory legislation of general application which Congress may from time to time enact for the protection of the public. It is also argued that by the Geneva Convention of 1929, which was ratified by the United States in 1932, the United States agreed to prohibit the use by private persons of the name and the symbol and that the Red Cross act and the Federal Trade Commission act should not be construed in favor of conduct which this nation is under international obligation to terminate.

We agree, however, with the court of appeals, said the Supreme Court. It is apparent from the terms of the 1905 and 1910 acts that Congress was concerned not only with protecting the Red Cross against pretenders but also with protecting the public against the false impression that goods purchased were the products of the Red Cross or were sponsored by it. Congress, however, did not go the full distance. It preserved the right of earlier, good faith users to continue the use of the words and the symbol. It may have concluded that the mark which had been acquired was a valuable business asset which should not be destroyed. Or it may have thought that the extent and manner of the use by the established concerns were not likely to injure the public. Whatever the purpose, continued the court, the fact remains that the good faith use of the mark by the pre-1905 users was intended to be preserved unimpaired. The court would not lightly infer that this specific right was to be swept away under the 1938 amendment to the Federal Trade Commission act; the problem is to reconcile the two acts, if possible, and to give effect to each. That could be done, the court thought, by recognizing that while the good faith use of the words and symbols by pre-1905 users is permissible, the commission may require the addition of language which removes any misleading inference that the products are in fact sponsored, approved or in any manner associated with the American National Red Cross. We only hold, concluded the Supreme Court, that under the facts of this case the commission may not absolutely forbid the use of the words and the symbol by the defendant. Accordingly the judgment in favor of the defendant was affirmed.—*Federal Trade Commission v. A. P. W. Paper Company, Inc., 66 S. Ct. 932 (1946).*

Unlicensed Physician as Expert Witness—The Supreme Court, appellate term, first department, held that it was error for the trial court to exclude the testimony of a medical witness, and a hospital record made at his direction, on the sole ground that the witness was not licensed to practice medicine in New York at the time the record was made.—*Black v. Ackerman, 63 N. Y. S. (2d) 445 (N. Y., 1946).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Board in Specialties were published in The Journal, Nov. 9, page 601.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, Jan. 21-23. Secretary, State Board of Medical Examiners, B. F. Austin, M.D., 519 Dexter Ave., Montgomery.

Delaware: *Examination.* Dover, Jan. 14-16. *Endorsement.* Dover, Jan. 21. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

District of Columbia:* *Reciprocity.* Washington, Dec. 9. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

Florida:* *Examination.* Jacksonville, Nov. 26-27. Sec., Dr. Harold D. Van Schaick, 2736 S.W. 7th Ave., Miami 36.

Indiana: *Examination.* Indianapolis, June. Exec. Secretary, Board of Medical Registration and Examination, Miss Ruth V. Kirk, 627 K. of P. Bldg., Indianapolis.

Kansas: Kansas City, Dec. 4-5. Secretary, Board of Medical Registration and Examination, J. F. Hassig, M.D., 905 North 7th Street, Kansas City.

Kentucky: *Examination.* Louisville, Dec. 16-18. Sec., State Board of Health, Dr. P. E. Blackerby, 620 S. Third St., Louisville 2.

Maryland: *Examination.* Baltimore, Dec. 10-13. Sec., Dr. E. H. Kloman, 1215 Cathedral St., Baltimore 1. *Homeopathic.* Baltimore, Dec. 10-11. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

Massachusetts: *Examination.* Boston, Nov. 19-22. Sec., Board of Registration of Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston 33.

Michigan:* Ann Arbor, Dec. 9-11. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

Minnesota:* Minneapolis, Jan. 21-23. Sec., Dr. J. F. Du Bois, 230 Lowery Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, Dec. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

Nebraska:* *Examination.* Omaha, June 1947. Director, Bureau of Examining Boards, Mr. Oscar F. Humble, State Capitol Building, Lincoln.

New Hampshire: Concord, March 13. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

North Carolina: *Examination.* Winston-Salem, Dec. 16-19 postponed. *Endorsement.* Raleigh, Jan. 16. Act. Sec., Mrs. L. McNeill, 226 Hillsboro St., Raleigh.

North Dakota: Grand Forks, Jan. 7-10. Secretary, Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

Ohio: *Examination.* Columbus, Dec. 3-5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

South Dakota:* *Examination and Reciprocity.* Vermillion, Jan. 21-22. Secretary, Board of Medical Examiners, Dr. Gilbert Cottam, State Capitol Building, Pierre.

Vermont: *Examination.* Burlington, Jan. 31-Feb. 1. Secretary, Board of Medical Registration, Dr. F. J. Lawliss, Richford.

Virginia: Richmond, Dec. 3-6. Secretary, Board of Medical Examiners, Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

Washington: *Examination.* Seattle, Jan., 1947. Secretary, Mr. Nelson Vaughn, Olympia.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: Dec. 10. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Colorado: Denver, Dec. 11-12. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

Iowa: Des Moines, Jan. 14. Corresponding Sec., Division of Licensure & Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines 19.

South Dakota: Sioux Falls, Dec. 6-7. Sec., Dr. G. M. Evans, Yankton.

Tennessee: Memphis and Nashville, Dec. 19-20. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis 3.

Wisconsin: Milwaukee, Dec. 7. Sec., Professor Robert N. Bauer, 152 W. Wisconsin Ave., Milwaukee 3.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days Three journals may be borrowed at a time Periodicals are available from 1936 to date Requests for issues of earlier date cannot be filled Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested) Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them

New Treatment for Vaginitis and Cervicitis.—Siegler believes that the ideal anti-infective agent should be buffered effectively so as to promote the reestablishment of the physiologically correct acidity and growth of Doderlein's bacilli consistent with a healthy vagina It should be antibacterial so as to control rapidly persistent infections especially in cervicitis requiring electrosurgery, it should be of such a physical consistency as to assure intimate and prolonged contact with vaginal and cervical mucosa, and it should be nonirritating and nontoxic These conditions are most closely approached by an acid jelly containing sulfathiazole, lactic acid, acetic acid, sodium tetradecyl sulfate and polyethylene glycol The jelly is nonirritating, nonstaining and of agreeable odor It spreads over the cervical and vaginal surfaces and is completely soluble in the secretions It does not easily leak out of the vagina unless the discharge is profuse It has a mild but definite astringent effect on the vaginal mucosa Use of the jelly has resulted in excellent control of vaginitis of trichomonal, monilial, gonococcal and nonspecific origin in 93 per cent of the cases studied, and in permanent cure in 83 per cent The period of convalescence can be shortened and annoying symptoms reduced by using the jelly before and after such procedures as conization coagulation, cautery and plastic repairs and other intravaginal surgery Healing was complete within an average time of five weeks, with a minimum of sequelae The convenience and simplicity of the single dose disposable paper applicator facilitates intravaginal medication in the office and in the patient's home

Time of Ovulation and Conception in Women—Farris determines ovulation by the reaction of the ovary of the immature white rat to the urine of the patient If ovulation is not taking place, the patient's urine has no effect on the ovary of the rat, if it is taking place the rat's ovaries become hyperemic Urine passed on arising in the morning is employed The test animal is an immature Wistar rat Two cc of the urine is injected subcutaneously into each of 2 animals At the end of two hours the rats are killed by illuminating gas Their abdomens are opened immediately Each ovary is inspected, and its degree of redness is compared with the colors of the Munsell color chart Observations were made on 88 married and 12 unmarried women Of the married women 76 wished to become pregnant Fifty of them had been inseminated artificially for periods varying from a few months to several years, with no conceptions resulting Most of the women who were tested showed a positive test for three or four successive days each month at the usually accepted ovulation time This is termed the normal reaction A few women showed a positive test for one or two days at approximately the same period sometimes followed by a day or more of negative test, then a second positive test for one or two days This is termed abnormal reaction Results thus far indicate the third or fourth day of a normal reaction as the time when insemination is most likely to produce pregnancy Women have not become pregnant in months in which they exhibited no reactions or abnormal ones

Irradiation of Nasopharyngeal Lymphoid Tissue.—Boies says that the lymphoid tissue of Rosenmuller's fossa and the nodules which occur in the mucosa of the orifice of the eustachian tube and within its lining are now considered to play an important role in early hearing loss in children In children 8 to 14 years of age there is a high incidence (nearly 40 per cent) of impairment of thresholds for some of the tones above C4, that is, for frequencies higher than 2,048 cycles per second A common cause of this hearing loss is to be found in the catarrhal changes of the middle ear which originate from infected lymphoid tissue in the nasopharynx Irradiation of pharyngeal lymphoid tissue is not new The author's observations of this treatment were made on 73 patients Small doses of radium or radon filtered so as to yield chiefly the beta rays seem effective in controlling the pathologic effect of small amounts of this tissue in its relation to the normal function of the eustachian tube The dose is so small that no local reaction is observed The role of hyperplastic lymphoid tissue in blockage of the eustachian tube has a new interest through observations of air corpsmen in whom the condition called aero-otitis media developed.

Laryngeal Tuberculosis.—Auerbach and his colleagues routinely examined the larynx in the course of necropsies for gross and microscopic pathologic changes. An opportunity was thus afforded to study the mode of development and the progression of laryngeal tuberculosis as well as its relationship to tuberculosis in other parts of the body. Laryngeal tuberculosis was present in 304 (37.5 per cent) of 811 cases of tuberculosis which came to necropsy. In all but 2 instances it developed as a direct infection from positive sputum in chronic pulmonary tuberculosis. Tuberculous foci, with and without central zones of caseation, form in the walls of the larynx as a result of tubercle bacilli which enter through the ducts of the mucous glands. Ulceration develops either through pressure atrophy of the mucous membrane by the tuberculous foci or by caseous necrosis of the overlying epithelium as the tuberculous areas enlarge. The further progression of the ulcerative process is similar to that in other parts of the body. Ulcers were found most frequently on the true vocal cords. Healing may occur in any stage of anatomic development, usually in cases in which underlying chronic pulmonary tuberculosis undergoes anatomic healing. In some instances healing and progression keep pace in the same larynx, resulting in a pronounced thickening of the wall, nodular protrusions into the lumen and narrowing of the canal.

Chloride Deficiency and Renal Changes.—Lowenhaupt and Greenberg say that chemical changes occurring in tissues and body fluids of rats fed a diet deficient in chloride consist in a lowering of the concentration of blood chloride, an increase of the concentration of blood bicarbonate and an increase of the urinary excretion of citrate, all indicative of chronic alkalosis. There is a characteristic shift in the water of the body, in which the apparent extracellular phase is increased in most of the tissues. As happens with most deficiencies, the growth of the rats is stunted. The deficient animals attained only about 50 per cent of the weight of the controls when the chloride content of the diet was reduced to between 2 and 5 mg. per hundred grams of food. A renal lesion uniformly develops in rats maintained on a chloride deficient diet. Early in the process calcium is precipitated in the lumens of collecting tubules, with consequent blocking and hydronephrosis. A granulomatous inflammatory response is a characteristic early reaction to the foreign material and to the degenerating tubular epithelium. Chronic alkalosis is suggested as the basis of the precipitation of calcium.

Experimental Atherosclerosis.—The feeding of cholesterol will produce atherosclerosis readily in rabbits and with more difficulty in guinea pigs. Attempts to obtain these vascular changes in rats, mice, cats, dogs, monkeys, goats, foxes, chickens, pigeons and parrots have been unsuccessful. Hypercholesteremia and atherosclerosis readily develop in the rabbit because this animal is unable to metabolize exogenous cholesterol. Since diets enriched with egg yolk have been shown to produce hypercholesteremia in man, monkeys and dogs without vascular sclerosis, Rosenkrantz and Bruger decided to extend this investigation to include white rats. They found that the prolonged feeding of egg yolk powder to rats augmented the cholesterol content of the blood and the liver but failed to produce atherosclerosis of the aorta. The lecithin content of the liver was not increased by the feeding of egg yolk. Deposits of fat appeared in the liver six to nine months after the feeding of egg yolk was begun. Under the conditions of this experiment the lecithin present in egg yolk failed to inhibit lipoid infiltration of the liver. During the latter months of the experiment the rats fed egg yolk powder gained weight more rapidly than did the control rats. The systolic blood pressure was not elevated in rats fed egg yolk powder.

Antireticular Cytotoxic Serum in Atrophic Rhinitis.—The serum used by Jackson was prepared in rabbits on the assumption that fewer persons would show allergic skin reactions following the injections. The dosage was 0.5 cc., 1 cc.

and 1 5 cc of a 1 10 dilution of the serum in saline solution hypodermically, with an interval of three days between doses No change was made in the patient's routine of life or nasal hygiene Five weeks after the last injection of serum the patients were reexamined The treatment was employed on 24 patients ranging in age between 22 and 70 years Twenty of the patients had atrophic rhinitis (ozena) and 4 had atrophic nasopharyngitis There was no improvement in the majority of patients, but a few showed some improvement mostly in subjective phenomena No change was noted in the size of atrophic structures The cause of the difference between these results and those reported by the Russians is not obvious

Infectious Hepatitis in Massachusetts —The clinical material used as the basis of this report was collected by visits to Massachusetts communities from which the disease was informally reported to the department of public health Approximately 175 cases of infectious hepatitis were uncovered in Massachusetts in these investigations, but only 151 case histories are used in this report, since in the remaining cases insufficient data were available The term "infectious hepatitis" is used to designate sporadic cases and "infectious epidemic hepatitis" for groups of cases during outbreaks The term "homologous serum jaundice" is used to refer to hepatitis artificially acquired from any source It is now held that infectious hepatitis is caused by a specific virus The disease confers lifelong immunity in most instances The transmission seems to take place by contact of a susceptible person either with a patient having the disease or with material contaminated by the causative virus It seems certain that the virus can be carried in food It may be carried in water Hardy and Feemster make a plea for the careful handling of infectious hepatitis, since the disease may cause irreversible hepatic changes and seems to be particularly serious in pregnant women Gamma globulin has no place in the treatment of the active phase of infectious hepatitis, but since it has been shown to be capable of producing passive immunity of six to eight weeks' duration it should be useful in the control of small outbreaks

*Analysis of Surgical Failures and Fatalities Following Thoracolumbar Sympathectomy for Essential Hypertension J W Hinton and J W Lord Jr —p 1714

Penicillin Aerosol in Bronchopulmonary and Sinus Infections.—Barach and his associates report improvements in the original technic of administering penicillin by inhalation, which consist in humidifying the aerosol by passing it over hot water and in eliminating large particles either by a baffle connected to the conventional nebulizer or by an especially constructed nebulizer, both procedures aimed to avoid irritation and red tongue The advantages of administering penicillin by inhalation can be discerned in lung abscess, in sinusitis and in selected cases of bronchiectasis, in each of which bacteria may grow on a fibromucopurulent surface that is not reached by a capillary blood supply The authors describe and illustrate new apparatus

Thoracolumbar Sympathectomy for Essential Hypertension —During the past four years Hinton and Lord have operated on 227 patients for essential hypertension, 152 being operated on by the Smithwick technic Beginning in June 1945 the authors started to extend the operation to the higher thoracic ganglions, and by December 1945 they were including from the third thoracic to the second lumbar inclusive in most operations and always through the fourth thoracic ganglion Twenty-six of the 227 patients died, a mortality of 11 5 per cent The immediate mortality was higher in the more extensive operative procedure The fatalities have been divided into three groups In group 1 all four major organs—eyes, cerebral vessels, heart and kidneys—were involved There were 15 cases in this group, and if the degree of involvement in each organ is graded from 1 to 4 plus, it was found that these 15 cases averaged 12 5 plus out of a maximum of 16 Operative procedure in these cases indicated poor judgment In group 2 there were three organs involved in 7 cases and they averaged 8 plus In group 3 there were two organs involved and 4 cases, with 8 plus In the latter two groups there was some justification for operation, as the organs were not completely damaged by the long standing essential hypertension The authors think that, if the degree of involvement in all organs exceeds 8 plus, it is questionable whether a thoracolumbar sympathectomy will give lasting results

Infection of Urinary Tract in Female Due to Trichomonas Vaginalis. B. Williams.—p. 63.

Embryoma of Kidney in Adult.—Thirty-five cases of Wilms' tumor have been reported in the literature; only 4 adult patients have survived for an appreciable time and 2 of these are known to be alive at the present time, ten and three years after nephrectomy. A third such case in a woman aged 35 is reported by Hill. Nephrectomy was performed and the removal of a lipoleiomyoangiosarcoma was followed by high voltage roentgenotherapy to the site of the tumor (3,500 roentgens). Microscopic examination of the specimen did not reveal any squamous cell nests such as have been described in some cases. The essential picture was of fatty, fibrous, muscular and vascular tissue composed of highly primitive cells showing varying and at times little differentiation, apparently originating from the renal blastema. Repeated examinations of the patient at intervals during the past five years have shown no evidence of recurrence, the patient having remained in good health.

Daniel Whistler and His Contribution to Pediatrics. H. P. Tait.—p. 325.

Serologic Aspects of Infectious Mononucleosis.—Dempster has analyzed 170 serums since 1943. The correlation is high between the clinical and the serologic diagnosis of infectious mononucleosis when the absorption test is used (66 per cent). The direct Paul-Bunnell test is of limited value especially in late and relapsed cases. In high titer cases (1:256) the direct test will suffice, but a considerable number of cases may never reach such high titer. Seronegative cases occur, but they form a low proportion of this series (26 per cent). Variations in titer occur during the illness. An application of Barrett's absorption technic to a series of cases in which serum therapy had been administered did not give satisfactory results, for complete absorption of the antibody, by either of the antigens employed, was not demonstrated. There appears to be a nonspecific stimulation of the normal heterophile antibody in acute febrile illnesses. An abridged absorption test may be employed in the routine serologic diagnosis of infectious mononucleosis.

*Gray Hair in Ill Nourished Children. Lucius Nicholls.—p. 201.

Blocking Antibody in Hay Fever.—Maunsell studied the development of the blocking antibody in specifically and in nonspecifically treated hay fever patients. Instead of injecting mixtures of isoserum and pollen into nonsensitive skin, the skin of the hay fever subjects was tested with mixtures of their own serum and pollen. A "direct" blocking test with autoserum was thus worked out with the object of detecting and titrating the inhibiting substance. Twenty-four allergic subjects who were sensitive to pollen only or to pollen and house dust were divided into two groups according to the treatment they received. In group 1 (11 cases) specific desensitization was carried out. The sensitive subjects received the routine course from 30 to 50 subdermal "pollaccine" injections, ranging from 20 to 100,000 Noon units per cubic centimeter. In group 2 (13 cases) nonspecific desensitization was attempted by the administration of unpooled human isoserum. The subjects received from three to six intravenous injections of from 10 to 30 cc. at intervals of a week. The serum was derived from nonallergic group A donors and given to the allergic recipients irrespective of their blood group. The development of a blocking antibody in the serum of specifically treated hay fever subjects was confirmed by this method. The blocking titer may be used as a guide for assessing clinical protection. No blocking antibody was detected in hay fever subjects treated with nonspecific injections of human isoserum.

Gray Hair in Ill Nourished Children.—Nicholls observed graying of the hair in children in Malaya aged between 5 and 12 years. The children had been in refugee camps. The hair of all the races of the tropics is black or nearly black; hence the diagnosis presents no difficulty, especially as the loss of pigment is seldom distributed evenly throughout the length of the hairs. It may be difficult to diagnose the condition in persons whose hair is fair. Pantothenic acid deficiency in black rats is followed by loss of pigment in the fur. Necropsies on these rats reveal necrosis of the adrenal glands, and the graying appears to be due to a loss of activities between one or more hormones and this vitamin. Some degree of graying of the fur of animals can be produced by other deficiencies than that of pantothenic acid; a deficiency of copper is an example. Most of the children observed by the author had been living largely on manioc root, and the vitamin deficiencies were multiple.

Eosinophil Granulomatosis. B. Beskow.—p. 965.

Significance of Tonsillectomy in Convalescents from Diphtheria.—Vaheri reports that tonsillectomy was done in 88 diphtheria convalescents from five to eight weeks after the outbreak of the disease to destroy the bacilli. In 52 of the 58 patients with pharyngeal diphtheria and in 21 of the 27 with nasopharyngeal diphtheria the bacilli disappeared within two weeks after the intervention. The results were good also in the 4 carriers operated on and in 2 of the 3 patients with nasal diphtheria. The control material of 600 diphtheria convalescents not operated on shows that the bacilli in diphtheria convalescents disappear more rapidly in cases treated with tonsillectomy. Five or preferably six weeks after the start of the disease is considered the time most suited for the operation.

Vertigo and Carbon Monoxide Intoxication with Vestibulocorticospinal Disturbance.—Nyman concludes that in vertigo of carbon monoxide intoxication the tipping and pointing reactions are not delicate enough to exclude higher vestibular changes of central origin and in part to localize these changes to the brain stem. Pathologic disturbance of the muscular tonus of central origin is regarded as the main cause of the disturbance of balance in cases of vertigo. The central disturbance may be a diffuse injury in the vestibulocorticospinal system, often with dominating functional changes of central origin.

Book Notices

Extensile Exposure Applied to Limb Surgery By Arnold K. Henry, M.B F R C S I Cloth Price $7 Pp 190 with 127 illustrations Baltimore William Wood & Company, 1945

This book on surgical exposure of deep lying structures of the extremities would lose much of its charm and usefulness without the author's preface and introduction In these few pages the purposes of the author are beautifully and forcibly portrayed It is his intent not only to lead the surgeon to the lesion most anatomically but to show the operator how to extend his incisions

The text is graphic throughout and is interspersed generously with the author's comments from well tried experience Detailed directions are given for each approach, and the intensely practical discussions are well correlated with the drawings The body of the text is well outlined and headed and paragraphed, all known methods of exploiting anatomic pathways, especially the cleavage lines and spaces, are described fully and graphically The author's manner is conversational throughout, a feature which makes for easy reading and comprehending His purpose is plainly that of teaching fundamental anatomy as it applies to surgery The figures of speech he uses and his literary style make the book pleasantly readable

The illustrations are admirable because they show the anatomic structures clearly. Wherever a maze of structures superimpose, the artist has illustrated them semidiagrammatically The drawings are clearly leader lined and the captions are large and legible Halftone cuts are used throughout, and the publishers have used paper of such a quality that the original drawings have lost little in reproduction The legends and sublegends are adequately explanatory Boldface type is used in the main legends, and the smaller type of the sublegends makes the drawings very clear. Together they epitomize the operative story

Narcotics and Drug Addiction By Erich Hesse, M D Translated by Frank Gaynor Translated published and distributed by authority of the Alien Property Custodian Cloth Price, $3 75 Pp 219 New York Philosophical Library, Inc 1946

This pseudoscientific treatise, apparently prepared for popular consumption (in Germany), attempts to give an overall view of the pharmacologic agents used by man throughout the world to gain a subjective feeling of well being and help him forget his troubles Material is presented on the chemistry, identification tests, pharmacology, abusive use, history, amounts consumed and effects of addiction The drugs discussed are classified either as 'truly dangerous poisons" or "relatively harmless ones" Among the former—or narcotics proper—are included opium and its derivatives, coca leaves and cocaine, mescaline, Indian hemp and intoxicating pepper. Alcohol, tobacco, the purines and cola are classed as "mere stimulants" The text represents a pitiful attempt to cover an enormous subject No new material is presented Studies reported during the past decade are ignored The discussions are often inadequate, and some errors in fact, translation or printing occur The section dealing with the opiates is particularly inadequate and antiquated The interested lay person would do much better to seek information in the Encyclopedia Britannica

Exercises in Human Physiology (Preparatory to Clinical Work). By Sir Thomas Lewis C B E F R S, M.D Physician in charge of Department of Clinical Research, University College Hospital London Cloth. Price $1 25 Pp 103 with 8 illustrations New York & London Macmillan and Co Ltd 1945

This booklet contains thirty three student laboratory exercises to be performed on human subjects either the medical students themselves or their laboratory partners The apparatus required is simple The directions are clearly given in the well known literary style of the late author The experiments include observations on vascular pulsation, blood pressure measurements, respiratory movements, effects of exercise, venipuncture, venous pressure, x-ray examination of the chest, electrocardiography, vasodilatation and sweating, colorimetry and blood flow, the plethysmograph the capillary microscope, the triple response, reactive hyperemia, effects of ultraviolet light, paralysis of cutaneous nerves, cutaneous sensation, superficial and deep pain, referred pain and peripheral effects of drugs It is stated by the author that this set of experiments is intended for the medical student in the transition stage between preclinical and clinical studies The booklet will be valuable to all who are engaged in teaching medical students and especially valuable to teachers in internal medicine and physiology The medical student will be impressed with the clarity and simplicity of the directions and the explanation of the observations One anglicism annoying to the American reader, is the expression of dosage in milligrams per stone of body weight.

A Standard Practice Manual for Use in State Hospitals for Mental Disorders By Henry Lee Johnson B Sc M D F A P A, Assistant Superintendent Western Oklahoma Hospital Fort Supply Oklahoma Fabrikoid Pp 79 Fort Supply, Oklahoma The Author, 1945

This little volume is divided into two sections The first, of thirty-nine pages, is designed for the physician in a hospital for mental diseases as a guide to the necessary clinical and statistical records and forms The second section is a ward manual for attendants, designed to acquaint them with the practices of the hospital, rules and regulations and instructions for emergencies. The volume is carefully compiled and can be adapted to most state hospitals It is far from being a substitute for training courses for either physicians or attendants but serves a useful purpose as a reference guide, particularly for the latter It should, indeed be required reading for each new ward employee. Dr Johnson has rendered a useful service to mental hospital administration

Dystonia musculorum deformans Por Austregesilo Jr, M D Pp 316 Rio de Janeiro Irmaos Di Giorgio & Cia 1945

After a chapter reviewing the work published from Schwalbe and Ziehen till the present the author discusses cases reports of which have been published and 14 cases of his own. He admits the influence of the hereditary, familial and congenital factors in the idiopathic form and the infectious, toxic and vascular factors in the production of the symptomatic dystonia musculorum deformans. The chapter on symptomatology is long and didactic In this chapter particular attention is merited by the studies of the cerebellar components The author concludes that there are two types of torsion dystonia, idiopathic (Ziehen-Oppenheim's disease) and symptomatic There are clinical and anatomic cases which must be included in the Wilson group Dystonia musculorum deformans is essentially a morbid manifestation of the extrapyramidal system in spite of absence of unequivocal lesions The lesions predominate in the basal ganglions, and the variety of localization in other centers explains the multiplicity of clinical motor manifestations

Synopsis of Obstetrics and Gynecology By Aleck W Bourne, M A, M B B Ch Consulting Obstetric Surgeon Queen Charlotte's Hospital, London Ninth edition Cloth Price $5 Pp 500 with 168 illustrations Baltimore William Wood & Company 1945

The mere fact that this is the ninth edition of this handbook affords proof of its usefulness and popularity The author states that it is not intended as a textbook but rather as a supplement to a textbook and is useful for students preparing for midwifery examinations For the sake of brevity all the material is presented in outline form The few illustrations are small and simply executed This compend is rather comprehensive, covering all of obstetrics including the newborn and gynecology. There is much that one could question but most of the teaching follows accepted opinion on the continent Most educators in this country have frowned on these medical digests prepared primarily to help students pass their examinations They provide little to the medical education of their readers

Regional Analgesia. By H W L Molesworth F R C S Senior Surgeon Royal Victoria Hospital Folkestone England Second edition Cloth Price 8s 6d Pp 92, with 12 illustrations London H K Lewis & Co Ltd, 1946

This edition has been published partly because many copies of the first edition were destroyed during the war A few changes have been included in the book and in general it can be said that it reflects the author's personal experience with regional anesthesia in various parts of the body together with a short chapter on spinal anesthesia and description of technic. In general, it would hardly satisfy the anesthesiologist as we know him today.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PREVENTION OF CONGENITAL MALFORMATION

To the Editor:—Please discuss preventive treatment for congenital malformations of the developing fetus in utero.

R. S. Averill, M.D., Lynden, Wash.

ANSWER.—According to D. P. Murphy (Congenital Malformations: A Study of Parental Characteristics with Special Reference to the Reproductive Process, Philadelphia, University of Pennsylvania Press, 1940, p. 97) the factors responsible for the production of congenital defects appear to be present in either the sperm or the egg cell prior to the time of fertilization. If this opinion is correct, a certain minimal number of congenitally malformed individuals will continue to be born at a more or less constant rate.

Two factors under human control can influence the birth rate of defective offspring. One of these is parental age, but only after 30 years of age does this factor assume any role in influencing the birth rate of congenitally malformed children. After this age there is a decided increase in the birth rate of defective offspring. For example, after the mother is 40 years of age the birth rate of congenitally malformed children is approximately three times the rate which is observed when the mother is less than 30 years old.

The second factor under human control which can influence the birth rate of malformed children is the previous birth of a malformed child in a family. In the general population a gross malformation, regardless of how slight, occurs with a frequency of about 1:200 live births. In contrast to this frequency, among the offspring of the parents of a malformed child, born subsequent to its birth, another malformed child will be born once in every eight births. In other words the parents of a malformed child are extremely likely to have another defective offspring.

Another factor which may influence congenital malformations is an attack of rubella in the mother during the first trimester of pregnancy. Avoidance of exposure to rubella during this period of pregnancy is therefore desirable.

There appears to be no way known at present to reduce the birth rate of congenitally malformed children except to follow the two suggestions mentioned, namely to limit reproduction to the years before 30 years of age, and for the parents of malformed children to have no more children.

DIZZINESS IN PREGNANCY

To the Editor:—What is the etiology, frequency and treatment of dizziness in normal pregnancy?

Donat R. Richard, M.D., Brooklyn.

ANSWER.—The symptom of dizziness or faintness is common during pregnancy, occurring on one or many occasions in the majority of women. There is no loss of consciousness but a feeling of lightheadedness. It is functional in origin, but a satisfactory explanation for its occurrence has never been given.

It is important to rule out organic disease whenever a patient complains of dizziness. It may be a symptom of anemia, cardiovascular disease, some abnormality of the eyes or ears or a manifestation of central nervous system disease. If there is no evidence of an organic basis for the complaint, simple measures usually suffice. The patient is reassured. She is told to sit quietly for a few minutes when the dizziness occurs. If these simple measures do not suffice, small doses of a barbiturate such as phenobarbital will be helpful.

X-RAY THERAPY FOR ATYPICAL PNEUMONIA

To the Editor:—What is the value of x-ray therapy in the treatment of atypical pneumonia? Would it be advisable to transport a patient by ambulance from home to an office for such treatment?

M.D., Arkansas

ANSWER.—On the evidence so far accumulated, it appears questionable whether x-ray therapy is of any value in the management of atypical primary bronchial pneumonia. Certainly the risk of transporting a sick patient to a hospital or office for x-ray therapy outweighs the possible value of the procedure.

BUTANE EXPLOSION BURN

To the Editor:—A patient received a second degree burn covering approximately 12.5 per cent of the body surface from the ignition of butane gas. Slight shock was present on admission and was treated with plasma. After recovery the patient was anesthetized and the burned area debrided and grossly cleansed. Petrolatum pressure dressings were then applied. Adequate amounts of plasma were given and other fluid balances were maintained. Penicillin also was administered. The urine output was good and there was no evidence of shock. However, the patient became unconscious twenty-four hours after admission, developed a fever of 102 to 105 F. and died sixty hours after admission. No autopsy was obtained. Is there anything peculiar about the physiopathology of butane burns?

M.D., Texas.

ANSWER.—The chemistry of butane or its combustion products does not explain the cause of the unexpected death mentioned in the query. Some special types of butane prepared for combustion purposes contain additives such as ether, but such additives are not known to introduce any factor which would influence the course of burns. Butane, a simple hydrocarbon, unit for unit, contains more British thermal units than its homologues methane and ethane, commoner constituents of combustion gas. For this reason the depth of a burn from butane might exceed that from equal flame exposure to the other gases mentioned. Butane does not possess any peculiar chemical property which may be regarded as significant in the fatal outcome of the case described.

TREATMENT OF STERILITY—TESTICULAR ATROPHY AFTER MUMPS

To the Editor:—Is there any treatment for bilateral testicular atrophy in a man aged 26 who is sterile after six years of marriage and who gives a history of double orchitis from mumps at the age of 10? He is well developed otherwise. Both testes are about the size of those of a 10 year old boy, or possibly a little smaller.

W. E. Anthony, M.D., Ottumwa, Iowa.

ANSWER.—If the patient has an azoospermia, treatment will not improve the condition. Apparently the patient has a testicular atrophy due to a previous orchitis. In such a condition there are extensive degenerative changes in the seminiferous tubules that cannot be altered by any treatment.

POSSIBILITY OF ADDICTION TO PAPAVERINE AND APOMORPHINE

To the Editor:—How long can papaverine hydrochloride in 60 mg. doses and apomorphine hydrochloride in 65 mg. doses be given without fear of addiction?

M.D., South Carolina.

ANSWER.—In Sollmann's Manual of Pharmacology, sixth edition, page 300, Himmelsbach is quoted as stating in 1937 that papaverine is nonaddictant. Apomorphine also does not produce addiction, since neither drug causes euphoria. The Federal Bureau of Narcotics has no record of addiction to either drug. They may therefore be administered without risk.

EFFECTS OF PENICILLIN AND SULFONAMIDES ON VIRUS PNEUMONIA

To the Editor:—Is there any experimental or clinical evidence to warrant the assertion that patients with virus atypical pneumonia are harmed by the administration of penicillin and/or sulfonamides?

M.D., Florida.

ANSWER.—While the evidence is plain that penicillin and/or the sulfonamides do not influence the course of atypical virus pneumonia favorably, there is no evidence that harmful effects have developed from the use of either one of these agents in the treatment of virus pneumonia.

DIAGNOSIS OF NEURODERMATITIS

To the Editor:—There are two signs which are valuable in the diagnosis of neurodermatitis which I do not believe have been reported to date and which are valuable enough in the diagnosis of this disease to bring it to the attention of other physicians. One of the chief characteristics of this type of dermatitis is the extreme itching that occurs. These persons are almost constantly rubbing their skin and irritating it. They often are found scratching at night when half asleep. One often sees them scratching while concentrating on various tasks such as *reading*. These persons seemingly never miss an opportunity to irritate their skin. The two signs based on this phenomenon are: 1. The patient will gently scratch the irritated areas if asked to demonstrate to a physician areas which itch. In other types of dermatitis the patient will point to it. 2. The nails of the patient are smooth and shining as the result of scratching with the flat (dorsal) surface.

A PLEA FOR A MORE CONSERVATIVE ATTITUDE IN RENAL SURGERY

Chairman's Address

ARBOR D. MUNGER, M.D.
Lincoln, Neb.

Just as in theology one has a conception of "original sin," so for the most part clinical observation impresses one that in the surgical treatment of diseases of the kidney the fetish for nephrectomy comes near to being the surgical "original sin." Renal pathology of sufficient moment to necessitate surgical interference presupposes organic or functional disturbance of such degree that the life of the patient or the integrity of the kidney or both are jeopardized. Recovery can be achieved in these cases by operative intervention. It is, however, unfortunate that this relief is obtained most frequently at the expense of extirpation of the kidney. To the urologist must go credit for the more comprehensive understanding of renal physiology, of anatomy and of the genesis of renal pathology—organic and functional. And yet it may safely be said that the surgeon who is doing renal surgery too often fails to make use of this new knowledge when its application favors a more conservative procedure.

The wide variety of lesions which one finds suitable for the newer methods of plastic technics or partial nephrectomy are legion. But, likewise, they challenge the judgment and technical ingenuity of the surgeon. Hydronephrosis is the commonest form of renal disease. Bell[1] has reported, exclusive of hydronephrosis due to renal calculi, an incidence of 3.8 per cent among 32,360 postmortem mechanical obstructions of an organic nature, namely: carcinoma of the prostate, bladder, uterus, ovary and rectum, with prostatic hypertrophy, uterine tumors and pregnancy as responsible agents for this high frequency and with only a small group of the congenital type.

It is toward this group of cases that a more universally conservative attitude is greatly to be desired. As Sargent[2] has aptly stated: "Witness, if you will, the fact that all general surgeons and a very large share of urologists themselves still confine their effort in the management of cases of ureteropelvic obstruction to two procedures—diagnosis and then nephrectomy." Let it not be assumed that nephrectomy is not necessary at times; it goes without saying that it is. But increasingly improved technics, the combination of plastic correction with partial nephrectomy and an understanding of renal physiopathology reduce to a minimum the necessity for nephrectomy.

Let me present some of these principles which serve to argue so well for conservative surgery. In the first place not all hydronephroses need surgical intervention. Pelvic dilatations of a fixed nature which produce no symptoms and in which the renal function remains unimpaired need no immediate operation. Reexamination every six to twelve months should be performed until one is satisfied that the condition is not progressive. The criteria necessary to make a choice between conservative surgical intervention and nephrectomy are, I believe, well delineated. One must consider (1) the functional value of the involved kidney, (2) whether the condition is bilateral or unilateral and (3) the presence and severity of infection. The factor of function in a kidney is of much more value than the size of the pelvic dilatation. If the clinician were to rest on the described pathologic changes which occur as the result of chronically increased intrapelvic pressure, then corrective plastic procedures would have but little place. On the contrary, clinically, it is astounding to see the great functional recovery, both tubular and glomerular, that a hydronephrotic kidney of this type will evidence.

In greatly dilated renal pelves containing a large amount of residual urine the usual functional dye tests are, as a rule, useless in the estimation of excretory integrity. It is here that an excretory urogram is of inestimable service. Early films show only a little puddling in the calices, but definitely increased density develops in the residual urine in one and two-hour films, to establishing the existence of a worthy degree of function.

I am not in sympathy with the oft expressed principle that a hydronephrotic kidney, if operated on at all, should be removed unless it is capable of carrying the total function in the event that the opposite kidney should be removed. Dodson[3] in his most recent book has stated that "Nephrectomy is usually indicated in large unilateral hydronephrosis with diminished renal function and a healthy compensating mate." This is a most depressing theory and lacks a basis in clinical fact, but certainly this statement in the mind of the general surgeon establishes an authoritative basis for nephrectomy.

Nor can a proper evaluation in regard to ultimate functional recovery be established by an indwelling ureteral catheter. Drainage established by a well instituted pyeloplasty will be the ultimate criterion to functional recovery. Rather than continue in a retarded state the reestablished kidney will extend itself to recover reasonable function.

Read before the Section on Urology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

Case 1.—Mrs. C., a woman aged 26, the wife of a soldier, came into my office with a decidedly generalized edema; the level of blood urea nitrogen was 127 mg. per hundred cubic centimeters; the blood pressure was 182 systolic and 80 diastolic. She was persistently nauseated, had violent headaches and progressive oliguria and was seven months pregnant. A history obtained from the husband and the patient revealed that a diagnosis of infected bilateral hydronephrosis with right renal calculus had been made one year previous in an army hospital. On the third attempt at corrective surgical intervention to the left kidney, ostensibly her better kidney, a nephrectomy had been performed in this army hospital. The infected right hydronephrosis with calculus was not corrected. As her pregnancy progressed the local and systemic manifestations from the pathologic condition in the residual kidney deepened until she appeared at my office with the symptoms detailed herein. She was immediately hospitalized, and a rapid pyelostomy was performed without attempting to remove the large calculus impacted in the ureteropelvic juncture. With the institution of proper intrarenal drainage and acceptable rehabilitative measures, this long standing, badly damaged and infected hydronephrosis made a remarkable functional recovery, and the patient assumed a normal clinical status except for a nonviable fetus which the consulting obstetrician relieved by cesarean section without incident to the patient. Several weeks later the right kidney was reapproached for corrective surgical intervention. The calculus was removed; part of the thickened redundant renal pelvis was resected away, and a sharply angulated, minutely calibered rigid stricture at the ureteropelvic juncture was split longitudinally and inlaid with a size 14 F gallbladder T tube, one end into the kidney pelvis and the other into the ureter. No attempt was made to cover the T tube in the strictured area, only tacking sutures to stabilize the tube in place. The kidney pelvis wound closed, and further pelvic or nephrostomy drainage was not instituted. On the twenty-eighth day the gallbladder T tube was removed and no leakage whatsoever occurred from the drainage tract. For the past four months this newly reformed ureteral area is being regularly calibrated with no. 9 bulbs and zealous apprehension. The patient maintains an infected urine of varying degree, a minimal residual urine, a blood urea nitrogen level within normal range, a satisfactory kidney function and absent local hydronephrotic symptoms. Clearly this kidney has emerged from a precarious chronic pathologic existence and is extending itself to carry on a normal physiologic career.

Congenital obstructive anomalies of the upper portion of the urinary tract tend to be bilateral. True it is, in most instances, that predominating symptoms and urologic observations present themselves in one kidney and the physician is prone to assume the obvious. However, a more minutely critical survey will reveal a bilaterality not indicated by the clinical symptoms. Thus, the removal of the manifestly hydronephrotic kidney in this circumstance throws an irreparable burden on the remaining member. There is an old saying that nephrectomy in the thirties for hydronephrosis leads to a hydronephrosis in the forties on the opposite side. To consider how this comes about, the manifestly hydronephrotic kidney, for example, may maintain a daily urinary output of 1,000 cc., whereas the ostensibly normal kidney maintains a daily excretion of 1,500 cc. Remove the damaged kidney, and the undamaged kidney, in order to maintain proper physiologic balance, attempts to assume the work of its removed mate and to excrete 2,500 cc. a day. Under this extra volume, an abnormal intrapelvic pressure builds up and starts pelvic expansion. However slight and unembarrassing is the obstructive process heretofore existing, it now becomes a matter of grave pathologic importance. A static urine of duration is invariably an infected urine. And it is safe to assume that all hydronephroses are infected lesions. The infection on urologic survey may not be palpably evident; however, once plastic surgery is undertaken active infection usually manifests itself. A careful cultural study is of the utmost importance. What with the proper application of the newer chemotherapeutic and antibiotic agents to augment the selected technical procedure along with the most essential principle of adequate and sufficiently prolonged drainage and of splinting where it is indicated, successful end results may be expected.

In only an occasional case will one be rewarded by disappearance of the infection. The restoration of adequate drainage, however, does lessen the residual urine and decrease the persistence of the invading organism. Slight residual pyuria or other sequelae are less disastrous than the destruction of function. I do not propose any individual successful pyeloplastic operation. The wide variety of plastic procedures applicable to this condition suggests that no single pattern holds advantage over another except as it may be especially applicable to the correction of the condition at hand.

The procedure of choice depends on the cause of the obstruction, which can be definitely determined only at operation. The ureteropelvic outlet may be distorted by extensive adhesions, fibrous or vascular bands and anomalous vessels. The juncture may be blocked by stricture, cysts, hypertrophied muscle or valve formation because of high insertion of the ureter. The plastic procedure that will correct the particular condition discovered should be chosen.

Except in far advanced cases, hydronephrosis due to obstruction at the ureteropelvic junction may be corrected by pyeloplasty, but the decision between pyeloplasty and nephrectomy is sometimes difficult to make unless severe infection is present or the pyelogram and appearance of the kidney at operation indicate the need for nephrectomy. If the obstructive lesion is extrinsic, pyeloureterolysis usually eradicates the obstruction. The presence and extent of intrinsic block is determined by probing the junction through a small incision, with a hemostat or a no. 12 or 14 F bougie. The caliber of the lumen should be measured and the degree of angulation noted. When stricture is encountered, the jaws of the hemostat are gradually spread to open the lumen while an incision is made to split the stricture throughout its length. The gap is bridged with a no. 12 or 14 ordinary gallbladder T tube left in place for three weeks. Epithelization around the tube ends will have occurred to form a new ureter.

When a hypertrophied muscle is encountered a row of parallel incisions are made down to the mucosa. Splinting and intubation are done through an incision below the hypertrophied muscle area with a no. 14 F tube to maintain the caliber of the lumen until healing is complete.

Obstruction from valve formation due to high insertion of the ureter into the pelvis is corrected by a suitable pyeloplastic operation, and the cut edges of the pelvis may be excised. An excessively redundant pelvis may be resected, and the ureter joined to the lowest part of the remaining pouch. Ureteral implantations or lateral anastomoses may also be utilized.

Anomalous veins may be sacrificed, but arteries should be treated with circumspection. The aberrant blood vessels to the lower pole of the kidneys are saved by a pyeloplasty by which the anterior and posterior walls of the pelvis are partially excised in such a way that, when sewed together, the ureter is in correct alinement. Nephropexy is performed as indicated.

Occasionally a renal sympathectomy is desirable to assure relief of pain.

Ureteral splinting and intubation, the most important single factor in the success of pyeloplasty, should be performed around the pelvis or ureter by any of the various methods suitable to the particular case. Splinting and intubation should be maintained for at least ten days to three weeks, or longer if necessary. The best adjunct to use for combined draining and splinting purposes is the ordinary gallbladder T tube.

Lesions of the kidney, which so frequently eventuate in nephrectomy, are in a surprising number of instances small lesions localized to a definite area of the organ with the rest of the parenchyma perfectly sound and the pyeloureteral excretory system corresponding to the same area perfectly intact. Nephrectomy frequently entails excessive mutilation and certainly often sacrifices the much needed healthy parenchyma surrounding a single and restricted lesion. In view of the vital importance of renal function, a more conservative method is essential. Partial nephrectomy has been in use since 1887 when Czerny first employed the method eighteen years after Simon had performed the first total nephrectomy. At that time an exact exploratory technic was not available. At present it is possible by urographic and other functional examination to determine more or less accurately the portion of the kidney which is affected, the cause of the lesion and the condition of the remainder of the organ, especially of the pyeloureteral excretory passage; therefore, conservative intervention can be carried out if the location of the lesion permits. Prior to surgical intervention, translumbar aortography (according to the technic of Reynaldo dos Santos[4]) may afford an exact knowledge of the morphology of the renal blood vessels, the condition of the portion to be saved and the location of the lesion to be resected. This is especially important if only one kidney remains or the contralateral kidney is diseased.

Indispensable prerequisites to partial nephrectomy are a normal blood supply to the portion of the organ which is to be saved and the absence of obstruction, assuring permeability of the excretory passages of this residual portion. The anatomic integrity of this portion must be previously ascertained and then verified at operation by manual examination and, if necessary, by direct roentgenography. Unless these conditions are satisfactory the resection should not be undertaken except in emergencies.

A study of extirpated kidneys with small, circumscribed lesions indicates that in many cases it is possible to remove the damaged portion without interfering with the function of the healthy residual portion. Conservation of one quarter of the total renal mass, or one half of one kidney, is sufficient and compatible with life.

Case 2.—Mr. C. S., a man aged 48, physically well set up, had a left nephroureterectomy for renal tuberculosis in 1939. At the time of his nephrectomy he had a known moderate nonspecific infection in the upper part of the urinary tract on the right side. Likewise, there was a bifid kidney on the same side. Under increased functional stress during the following year there developed multiple calculi with increasing pyelectasis in the lower pelvis of the residual kidney. Progressively severe local and systemic symptoms made it necessary to interfere surgically. On inspection, the upper half of the kidney, the ureter and blood supply appeared normal. The lower half of the kidney was soft, distended and bluish—definitely a case of calculous pyonephrosis. This pyonephrotic lower half with its ureter to the bifurcation was amputated through a rather bloodless suggestion of a septum. This residual portion of the right kidney has been sufficient to enable the patient to live normally for nearly six years with manifestly fewer signs of renal insufficiency than existed before the partial nephrectomy (fig. 1 *A*).

As a rule, it is possible only at operation to determine whether or not partial resection is possible, although pyelography is also of great value. Partial nephrectomy is indicated in all cases in which the lesion affects less than one half of the organ; in exceptional cases smaller portions may be saved. The method is especially indicated in partial or localized hydronephrosis affecting the parenchyma of one or two calices or one polar extremity of the organ. If the operation is supplemented by proper pyeloureteral correction to assure subsequent drainage of the residual portion, the results are certain. In lithiasis affecting a large zone, in which simple extraction of the calculus is not sufficient, partial nephrectomy will permit conservation of the remainder of the parenchyma and prevent progress of the lesion due to contact of the healthy tissue with the inflammatory process (fig. 1 *B*, *C*; fig. 2). In renal cysts partial nephrectomy is indicated if the cysts are restricted to one

4. dos Santos, R.: Med. contemp. 47:93, 1929.

zone; this is frequently the case with large solitary cysts. Partial resection is indicated in some cases of hydatid cyst, provided the cyst can be removed with the affected portion and communication does not exist between the cyst and the calices or renal pelvis (fig. 3 *B*).

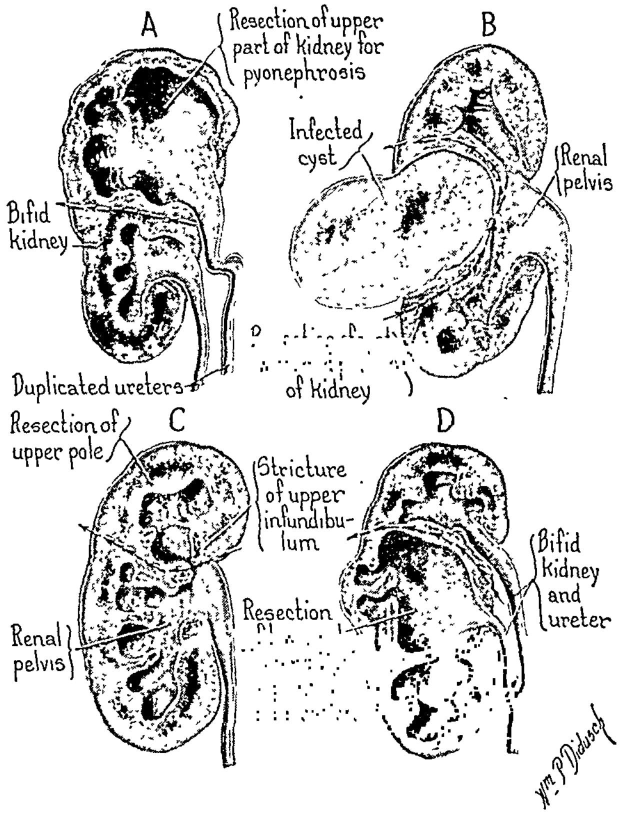

Fig. 3.—Partial resection in cases of localized destructive renal infection (*A*, *C* and *D*) and hydatid cyst (*B*).

Partial resection is indicated when it is necessary to remove abnormal blood vessels which alter or impede pyeloureteral evacuation, with resultant permanent or temporary pyelorenal ectasis. If the renal area supplied by this vessel is greatly changed (atrophic, infected) the superimposition of circulatory disturbances inherent in the ischemia produced by section of the vessel may easily lead to septic necrobiosis of that zone, and the septic process may extend to other renal areas. In these cases it is advisable to extirpate the portion affected by the ischemia in order to avoid this danger and save the remainder of the organ. In certain plastic pyeloureteral interventions it may be necessary to extirpate a portion of the kidney (fig. 1 *D*).

In destructive renal infection localized in one restricted portion of the organ, extirpation of this zone and direct drainage through the surface may save a considerable portion of the kidney. This has been found effective in abscesses of the renal cortex, renal infarction, localized pyonephrosis and perirenal abscesses invading the organ by contiguity (fig. 3 *A*, *C* and *D*).

It is conceivable that partial nephrectomy may be employed in renal tuberculosis, especially if there is coincident complete pyeloureteral duplication, permitting functional and roentgenographic examination of each excretory system independently. If careful functional tests (and especially retrograde pyelography) indicate that one portion of the duplicated kidney is completely intact and if at operation the vascular condition and the degree of extension of the infection will permit it, extirpation of the tuberculous duplication would be indicated.

In pyelic and pyeloureteral anomalies with infection involving only one portion of the kidney, and in which the remaining excretory system is adequate for the accumulation of the urine secreted by the healthy kidney, partial nephrectomy is indicated (fig. 4). Authorities are not in accord as to the value of partial nephrectomy in renal neoplasm. Favorable results have been reported in benign and restricted cases. Czerny performed the operation in a case of angiosarcoma of the kidney. Renal fracture offers a most satisfying field for the exercise of conservative judgment. Almost irrespective of how badly shattered is the renal parenchyma with an intact renal pedicle, and even though it is of a number of days' duration, with a large retroperitoneal accumulation of blood and urine, infected or not, after the gathering together of the fragments in some semblance of a mass, protected by gauze pack and wide open drainage, the kidney will astoundingly recover and will reestablish a satisfactory pyeloureteral excretory system.

In all cases the surgical indications depend on the anatomic condition of the organ and the lesion and on the condition of the contralateral kidney. I consider that it is preferable to risk failure of conservative treatment, necessitating intervention, rather than to remove a kidney which might have been saved in whole or in part. One disadvantage of the partial resection which has prevented more extensive adoption of the method is hemorrhage of the sectioned surface, together with the difficulty of obtaining hemostasis. Systematic use of the electric bistoury for section of the renal parenchyma reduces the severity of this immediate complication. Another disadvantage, hitherto, has been the difficulty of determining the exact zone affected by the lesion. However, modern exploratory and roentgenographic methods render localization of the lesion and confirmation of the integrity of the remaining renal area possible prior to or during operation.

Two fundamental technical details must be observed in partial nephrectomy: (1) previous ligation of the prehilar vascular system of the portion to be extirpated and (2) suture of the bleeding surface of the kidney, supplemented by the application of a muscle tissue graft, thrombin topical and desiccated fibrin film over the bleeding area to afford better hemostasis. The graft may be obtained from the margin of the lumbar operative incision. The muscle tissue reinforces the sutures in the friable tissue of the renal parenchyma. The institution of drainage is decidedly important and may determine the success of the intervention. If the excretory passages, renal pelvis or calices have been opened and are closed by suture, intrarenal drainage is essential and should be continued for from fifteen to twenty days until perfect coaptation of the pyelorenal suture is assured. Drainage removes the danger of urinary fistula, which might interfere with the ultimate conservative results. Perirenal drainage near the bleeding surface should never be omitted. It should be maintained for at least eight days to prevent the retention of any suppurative material. Lack of communication with the external surface favors abscess formation, with possible extension of the infection to the other parts of the kidney.

SUMMARY

1. There are too many nephrectomies.
2. The surgical correction of hydronephrosis is for the most part a perfectly logical and feasible operation.
3. Hydronephrosis is commonly a bilateral disease.
4. Protective splinting with adequate and prolonged intrapelvic drainage is an absolutely necessary procedure in plastic correction of the renal pelvis.
5. About 70 per cent of diseases requiring surgical intervention and of congenital malformation of the kidney are amenable to partial nephrectomy.
6. Total nephrectomy in hydronephrosis should be instituted only when it can be demonstrated that the drainage system is completely destroyed beyond recovery and in renal disease wherein it can be shown that the kidney is utterly worthless.

1015 Sharp Building.

Birthday of Atomic Energy.—Major Gen. L. R. Groves, commanding general of the Manhattan project, said that the significant anniversary which should be observed in connection with the United States program of development of atomic energy is December 2. It was Dec. 2, 1942 when the first successful nuclear reactor was made to work. It was built under the West Stands of Stagg Field at Chicago by a group of scientists working under Arthur H. Compton at the Manhattan project's metallurgical laboratory. That was the day on which man first demonstrated that not only could he release the energy of the atom but he could control it. A special meeting of representatives of the Argonne National Laboratory and its twenty-five participating universities will be held in Chicago on December 2, the fourth anniversary of the first self-sustaining pile.

NEUROLOGIC COMPLICATIONS OF SPINAL ANESTHESIA

MORRIS J. NICHOLSON, M.D.
and
URBAN H. EVERSOLE, M.D.
Boston

Neurologic complications, although infrequent, may follow spinal or general anesthesia. There are reports in the literature of cranial nerve palsies,[1] hemiplegia[2] and peripheral neuropathies[2a] following general as well as spinal anesthesia. Certain neurologic complications are prone to follow spinal anesthesia while others are more frequent after general anesthesia. Woltman found that convulsions, extrapyramidal rigidity and postoperative psychosis followed general anesthesia almost exclusively.[2a] Courville has shown that the anoxic hypoxia associated with the administration of such weak anesthetic agents as nitrous oxide and ethylene can cause degenerative changes in the cerebral cortex and lenticular nucleus.[3] On the other hand, headache,[2] septic[4] and aseptic meningitis,[5] arachnoiditis,[6] neuritis,[7] myelitis[8] and the cauda equina syndrome[9] have been the complications most frequently reported following spinal anesthesia. It is on these complications, particularly the cauda equina syndrome, that our attention will be centered.

These cauda equina complications are generally brought to the anesthesiologist's attention because the patient fails to regain the use of his lower extremities at the usual time following spinal anesthesia. On examination, loss of motor and sensory function is generally found to involve the lumbosacral nerve distribution. Associated observations are urinary retention and incontinence of feces with the loss of anal sphincter tone. This loss of bowel and bladder function is the most ominous part of the entire clinical picture, and the return of function, when it occurs, is extremely

slow. Impairment of sensation seems to be exceedingly variable. This loss of sensation may involve only the saddle area, one or both legs or the entire body below the umbilicus. Ferguson and Watkins[9b] felt that it was clear from the examination of all their patients that the basic lesion was the same (cauda equina) but the variations were due to different degrees of affection of this area.

ETIOLOGY

The exact cause of each of the neurologic complications that have been reported following spinal anesthesia in man is difficult to determine. Several investigators have shown that certain spinal anesthetic drugs cause a specific toxic destructive effect on nerve tissue when they are injected intrathecally in the dog or cat. Davis and his associates,[10] after injecting dibucaine (Nupercaine hydrochloride), a solution of procaine, amyloprolamine, alcohol and strychnine sulfate (Spinocain), a solution of procaine 40 per cent containing a small amount of strychnine (Gravocain) and procaine hydrochloride (Scurocaine) intrathecally in dogs, observed the following changes: (1) a varying degree of inflammatory reaction in the leptomeninges; (2) passive changes in the ganglion cells of the gray matter of the cord similar to those seen in retrograde or so-called wallerian degeneration; (3) swelling and fragmentation of axis cylinders, and (4) signs of degenerative changes in the fiber tracts of the cord. Lundy[11] was able to show degenerative changes in the nervous structure in dogs when they were exposed to 20 per cent concentrations of procaine hydrochloride but was unable to show the same degenerative phenomena when the concentration was less than 17.5 per cent. MacDonald and Watkins,[12] in an attempt to explain the damage to the cauda equina caused by heavy Durocaine[13] in human beings as reported by Ferguson and Watkins,[9b] used cats for their experiments. First, they administered the gliadin, glycerin and alcohol which had been added to the procaine hydrochloride to make the Durocaine to find out what effect these drugs would have on the cauda equina of cats. They were unable to produce paralyses in cats by the intrathecal injection of 15 per cent alcohol with 20 per cent glycerin. In using solutions of the same concentration as that employed in man but of greater relative bulk, however, they were able to reproduce the lesions of the cauda equina with heavy Durocaine in a considerable proportion of the cats. They could also produce such lesions by injection of procaine hydrochloride itself in the same concentration, 10 per cent, as that employed in man. Furthermore, the incidence of these lesions in cats was greatly increased by employing a stronger concentration of the drug. There seems to be little doubt, therefore, that the toxicity lies within the spinal anesthetic agent itself when the cat or dog is the subject.

The clinical manifestations of the lesion of the cauda equina might be explained by damage to the lumbosacral region of the cord, to the conus medullaris or to the nerves of the cauda equina, but it seems more probable that the maximal damage is to the latter. It seems rather evident that the lesion produced is the direct result of the administration of a spinal anesthetic agent, since in most cases it has occurred immediately following the operative procedure. A discussion of several possible ways in which such damage might occur follows.

Direct Trauma.—Direct trauma as the sole cause of the anesthetic complication can fairly well be eliminated because of the tens of thousands of diagnostic lumbar punctures, some of them with much trauma, that have been performed without any similar complication. But there does seem to be a definite relationship between the traumatic spinal puncture, which causes pain to radiate down the leg and which is combined with the injection of a spinal anesthetic drug, and a permanent neurologic complication.

Inflammatory Reaction.—The rapid onset of most of these complications seems to preclude infection as the etiologic factor. Furthermore, no organisms have ever been cultured from the spinal fluid of a patient with this type of lesion, and the dominating cells are generally lymphocytes rather than polymorphonuclear leukocytes. Seldom are there complications associated with an elevation in temperature or other signs and symptoms of an inflammatory process involving the protective coverings of the spinal cord. On exploration of the spinal cord the day after the administration of the spinal anesthetic in case 1, there was slight, if any, evidence of inflammation.

Toxicity of the Drug.—In considering whether these lesions of the cauda equina in man are due to the toxicity of the agent itself, as has been shown to be the case in the dog and cat, it should be noted that not all the nerves influenced by the anesthetic agent are affected by the paralysis. The truth of this observation is clearly illustrated in the reports of cases in which the anesthesia would suffice for an upper abdominal operation and yet the ultimate paralysis would be limited to the lumbosacral or sacral nerves. It seems that only those nerves exposed to the greatest concentration of the drug are affected. Permanent paralysis, then, seems to be greatest in the nerve tissues (nerve roots, conus medullaris and sacral region of the cord) which meet the drug in its full concentration soon after it has left the tip of the spinal puncture needle. The lesion is, therefore, maximal in those roots of the cauda equina into the immediate vicinity of which the drug is injected. The evidence of the experiments on animals leads to the conclusion that this is not in the nature of an idiosyncrasy, as postulated by Brock, Bell and Davison,[8] but that in the concentrations employed most spinal anesthetic drugs have a toxicity little short of that which would produce paralysis in a higher percentage of patients. The cystometric studies of Bellis[14] also showed what a profound effect spinal anesthesia and general anesthesia have on this part of the cord.

Neurologic Disease Precipitated by Spinal Anesthesia.—Another consideration in the etiology of these complications is the possibility of spinal anesthesia acting as a precipitating factor in the evolution of certain preexisting neurologic affections. Hammes[15] reported 8 cases in which neurologic complications were associated with spinal anesthesia; 5 involved the following preexisting organic neurologic disorders: pernicious anemia with combined sclerosis, multiple sclerosis, tabes, general paresis and toxic psychosis. Additional evidence that this supposition may be true is gained from cases 2 and 3 in which the patients received spinal anesthesia for the removal of carcinoma of other parts of the body, only to have the anesthesia fail to wear off. Subsequent investigation revealed that the carcinoma had already metastasized and was producing an almost complete blockage of the circulation of the cerebrospinal fluid. That the routine diagnosis of such impending blockage of the cerebrospinal fluid is difficult has been pointed out by Poppen and Hurxthal[16] in their attempt to explain why some patients with known tumors of the spinal cord have normal spinal fluid dynamics. They feel that in spite of the presence of pathologic change, the spinal fluid dynamics will be normal until the opening in the subarachnoid space becomes smaller than the opening in the spinal puncture needle used in the determination.

INCIDENCE

It is almost impossible to determine from the literature the true incidence of neurologic complications following spinal anesthesia, since the reports show a great variation. Early in his experience with spinal anesthesia Babcock[17] reported several abducens palsies, but subsequent to this early experience he reported the administration of 15,000 Stovaine (the hydrochloride of benzoyl dimethylaminoethyl-propanol) spinal anesthetics without neurologic complications. Livingstone and her co-workers[5] gave the incidence of aseptic meningitis as 1 in 2,000, while Hyslop[18] found an incidence of 0.5 per cent of sequelae in the central nervous system after spinal anesthesia. Falk[19] reported a 6 per cent incidence of headache with associated stiff neck. Jarman[20] gave the incidence of paralysis as 1 in 1,000, while Emmett[21] after 1,415 and Foss and Schwalm[22] after 3,000 spinal anesthetics observed no neurologic complications. Ferguson and Watkins[9b] reported 14 cauda equina syndromes following the use of heavy Durocaine in 1,000 cases at the Manchester Infirmary in England over a two and a half year period. During the same period there were 1,000 patients who received Stovaine spinal anesthesia, 300 dibucaine, 860 light Durocaine and 650 whose spinal anesthetic agent was not listed. This makes a 1 to 271 incidence of permanent neurologic complications for the entire group, but since all the complications were with heavy Durocaine, the incidence for this drug is 1 to 71.

In a report on 1,381 patients who received Metycaine hydrochloride spinal anesthesia at the Lahey Clinic, Woodbridge[2b] found 4 patients who suffered a transient foot drop. Although the anesthetic was the most likely etiologic factor, trauma from tight bed clothes may have been a contributing factor in these cases. Fortunately, all 4 of these lesions cleared up completely in six months.

According to Woltman,[23] the ulnar and peroneal nerves are the most frequent sites of peripheral nerve paralyses. He was of the opinion that senility, arterioscleroses, infectious neuritis and trauma must be considered as important factors in the etiology of these neuropathies. Trauma may result from faulty position on the operating table or from the patient's crossing his legs. The latter is especially important when there has been decided loss of weight from a prolonged illness or a serious operation.

There have been 21,000 patients at the Lahey Clinic who have received tetracaine (Pontocaine) hydrochloride for spinal anesthesia since 1934. Five neurologic complications have resulted. In 3 of these patients there developed lesions of the cauda equina type; 2 of the patients were later found to have a cerebrospinal fluid block from metastatic carcinoma. Two developed a peroneal neuropathy which was manifested by foot drop. In addition, 2 patients in whom there developed postspinal neurologic disturbances and who were suspected of having permanent sequelae were found on further investigation and operation to have been suffering from tumors of the spinal cord.

REPORT OF CASES

The following reports of cases in which neurologic complications developed after spinal anesthesia have been obtained from the records of the Departments of Anesthesiology and Neurosurgery of the Lahey Clinic and from the records of certain other anesthesiologists and surgeons outside the Lahey Clinic who have a particular interest in this problem.

Cauda Equina Syndrome

CASE 1.—A white man aged 42, a bartender, was seen Nov. 9, 1943 with the complaint of cold legs of two years' duration and cramps in the calf muscles of six months' duration. A diagnosis of thromboangiitis obliterans was made, and hospitalization for further investigation and a possible lumbar sympathectomy was advocated. On Feb. 26, 1944 he was given 14 mg. of tetracaine (Pontocaine "Niphanoid") hydrochloride and 2.6 cc. of 10 per cent dextrose for skin temperature readings; spinal puncture was made in the third lumbar interspace. Anesthesia developed to the eighth thoracic segment. After twenty hours the anesthesia was still present, and the patient was paralyzed from his waist down. A spinal puncture at that time showed an initial pressure of 50 mm. of water, total protein 347 mg. and sugar 21 mg. per hundred cubic centimeters and lymphocytes 57. Approximately thirty hours after the spinal anesthetic was administered, an exploration of the lower thoracic and upper lumbar cord under endotracheal ether anesthesia for what was thought to be a spinal fluid block was performed. No block was found; the cord showed only slightly increased vascularity and injection. The patient remained in the hospital three months and showed but little improvement. There was some improvement in sensation over the area supplied by the second lumbar nerve and a slight return of motor power in the feet. Although he voided voluntarily, there was a persistent small amount of residual urine with an associated pyuria present throughout his hospital stay. He was discharged from the hospital without ever having regained the use of his lower extremities. During his stay at home over the next fourteen months there was no improvement in his condition. He died eighteen months later, and a complete necropsy, including the brain and spinal cord, was obtained. The pertinent pathologic observations were in the spinal cord.

The following is a comment by the neuropathologist: "The principal pathologic observation is the loss of nerve fibers in the roots of the cauda equina and the regeneration of fine nerve fibers in the anterior roots. The degeneration of posterior columns of the spinal cord is unquestionably secondary to destruction of posterior roots. The fibrous thickening and cellular proliferation in the meninges may be viewed as the final stage of an inflammatory process whether induced by chemical irritation or infection. The pathologic observations are approximately the type one would expect in a lesion one to two years of age. The partial sparing of some roots and the regeneration in others would account for the retention of some bladder function and sensation. There are no vascular lesions suggestive of thromboangiitis obliterans. I believe that the changes in the anterior roots which were interpreted as neurofibromatosis are regenerative phenomena. The observations are consistent with, although not pathognomonic of, the cauda equina syndrome of spinal anesthesia."

Case 2.—A white woman aged 49 had had two previous spinal anesthetics, the first on Jan. 31, 1945 for a diagnostic curettage, at which time she was given 7 mg. of tetracaine hydrochloride with dextrose. The next day she was given, by the continuous method, 12 mg. of the drug with dextrose for the excision of a right ovarian cyst which showed papillary adenocarcinoma.

Three months later the patient underwent another operation, this time at the Lahey Clinic, and tetracaine hydrochloride-dextrose spinal anesthesia by the continuous method was used. The height of anesthesia was never satisfactory, although 38 mg. of the drug was eventually injected. The level of anesthesia never went above the eleventh thoracic segment, and it had to be supplemented by the administration of cyclopropane plus curare intravenously so that a hysterectomy and appendectomy could be accomplished. The pathologic sections showed uterine carcinoma of an undifferentiated type. Seven hours after the operation the patient was still unable to move her legs. A lumbar puncture was performed which revealed a block approximately at the eleventh thoracic segment. The subarachnoid space was irrigated with isotonic solution of sodium chloride and the patient seemed to get a slight return of sensation. A laminectomy performed May 11, 1945 under endotracheal ether anesthesia revealed metastatic carcinoma to the cord, dura and vertebrae. The patient died six weeks after the onset of her neurologic complication without ever manifesting any real return of motor function to her legs.

Case 3.—A white man aged 57 had an exploratory laparotomy on July 20, 1945 under tetracaine hydrochloride-dextrose continuous spinal anesthesia plus intravenous pentothal sodium. Far advanced carcinoma of the fundus of the stomach with widespread metastases to the pelvis, retroperitoneal nodes, chest wall and liver was found. Twenty-four hours later the patient was still paralyzed from the umbilicus down. Spinal puncture at the fourth lumbar interspace showed a blockage of the cerebrospinal fluid; the subarachnoid space was flushed out with isotonic solution of sodium chloride, but the patient failed to show a return of motor function. The paralysis, which was felt to be on the basis of a metastatic carcinoma to the vertebrae and structures surrounding the cord, persisted.

Cases 2 and 3 bring out the danger that spinal anesthesia will precipitate a neurologic disease which already exists, and these cases also demonstrate the toxic properties of anesthetic agents when the local concentration is too high.

Case 4.—A white man aged 66 who had lost considerable weight underwent a subtotal gastric resection for carcinoma of the stomach on April 3, 1945. Twenty milligrams of 1 per cent tetracaine hydrochloride mixed with one and a half times as much 10 per cent dextrose was given in two doses by the continuous method to provide anesthesia for a two-hour operative procedure. The patient made an uneventful recovery and was discharged from the hospital. On a subsequent visit two months later, he was found to have a left foot drop. No other neurologic observations were discernible on physical examination. The opportunity for a follow-up study on this patient was interrupted by his death in October 1945, seven months after his operation, from recurrence of his original disease.

Case 5.—A white man aged 43 had undergone a cholecystectomy four years prior to Dec. 10, 1945 when he was seen at the Lahey Clinic because of persistent jaundice. Eight days later a repair of a common duct stricture was performed under tetracaine hydrochloride-dextrose continuous spinal anesthesia with a cyclopropane supplement. A total of 26 mg. of the tetracaine was used over a three hour period. When the patient was allowed out of bed following this operation, he noticed what he thought was some weakness in his right ankle. Three months later there was definite weakness of the dorsal flexors of the right foot as well as of the posterior tibial and peroneal muscle groups. On comparing the size of his two legs, the right calf was ¾ inch smaller than the left.

Patients Suspected of Having Postspinal Neurologic Complications

Case 6.—On May 27, 1944, a 58 year old white woman was given a spinal anesthetic consisting of 17 mg. of 1 per cent tetracaine hydrochloride plus 1.8 cc. of 10 per cent dextrose for the repair of a cystocele, rectocele and uterine prolapse. The anesthesia was satisfactory for an operation of one hour and forty minutes, and its maximum height reached the tenth thoracic segment. Three to four months after this operation the patient complained of severe pain in both legs, and this was gradually replaced by a feeling of numbness and a loss of strength which caused her to fall rather frequently. Her legs soon grew so weak that she was confined to bed. On admission to the hospital twenty months after her operation she had a cord-type bladder with an overflow incontinence. She had a loss of sensation to pin prick extending cephalad to the sixth thoracic segment. Diagnostic lumbar puncture revealed an almost complete cerebrospinal fluid block with an initial pressure of 100 mm. of water and a total protein content of 122 mg. per hundred cubic centimeters. On Feb. 15, 1946 under endotracheal ether a spinal cord tumor (meningioma) was removed opposite the sixth and seventh cervical segments. The patient made a satisfactory recovery.

Case 7.—On March 27, 1945, a 40 year old white woman was given 17 mg. of 1 per cent tetracaine hydrochloride and 2.5 cc. of 10 per cent dextrose for the removal of her gallbladder. Light cyclopropane supplementary anesthesia was administered to render her unconscious. A curare preparation had to be given intravenously to facilitate closing the peritoneum after one and one-half hours had elapsed, as the patient's abdominal muscles were no longer relaxed.

During her postoperative convalescence she complained of some pain in her right leg, hip and ankle and had an unexplained elevation of temperature. Although the signs were not definite, anticoagulation treatment was instituted on the assumption that she was suffering from a pelvic thrombophlebitis. At the end of three weeks, after being up and around the ward for two days, she left the hospital.

Eight months later the patient was readmitted to the hospital because of an obvious neurologic disturbance in the function of her legs. The reflexes were hyperactive at the knee and ankle, and clonus was present. She could raise her left leg, but all motor power in her right leg was absent except for some slight motion in the toes. A loss of sensation was elicited to the tenth thoracic segment. Constipation caused much concern, as did an alternating urinary frequency and incontinence.

On Dec. 14, 1945 under endotracheal ether anesthesia a laminectomy was performed from the seventh thoracic to the first lumbar segment, and lysis of arachnoidal adhesions and constricting bands with decompression of the spinal cord was carried out. An intramedullary tumor at the level of the eighth and ninth thoracic segments was seen, and around this area the arachnoid was decidedly thickened with dense adhesions to the cord. Postoperatively the patient showed slight improvement with some return in motor function of the legs. Many of her neurologic signs persisted, however, and she was advised to have deep radiation therapy, which she refused.

Patients Seen in Consultation

Case 8.—In September 1940 a white woman aged 44 received 16 mg. of tetracaine hydrochloride with 3 cc. of dextrose for a cholecystectomy. Anesthesia did not wear off. The patient showed typical signs of a cauda equina injury, with loss of bowel and bladder function and loss of motor function in the legs. This persisted for eight months, but gradually she obtained a return of motor function and was able to walk. She had signs of a cord bladder and the rectal sphincter was relaxed. After being able to carry on normal activities, she gradually grew worse and lost the use of her legs. In 1943 a laminectomy was performed for the relief of arachnoidal adhesions. During the postoperative period her atonic bladder was treated by tidal irrigation according to the method described by Munro,[24] and this caused appreciable improvement in bladder function. Following the release of the arachnoidal adhesions there was improvement in the motor function of her legs, but this improvement has not been sustained and a gradual retrogression has ensued. On examination in September 1945, spastic paraplegia with mass-type reflexes was found to be present. The saddle area was anesthetic, and there was loss of sensation to pinprick up to the eighth thoracic segment. Her bladder is of the atonic type, and the anal sphincter is relaxed. This patient, now almost totally paralyzed below the waist, is a problem in rehabilitation and will need the special care described by Munro[25] to control her spastic paraplegia and her urinary difficulties.

Case 9.—On May 25, 1943 a white man aged 42 was given a spinal anesthetic of tetracaine hydrochloride plus dextrose for repair of a left inguinal hernia. The surgeon said the induction of anesthesia was unsatisfactory, as the patient was able to move his legs for one-half hour. Twenty-four hours later he showed loss of bowel and bladder function, with almost complete motor paralysis of his legs. All this was reported to have cleared up in three weeks.

When seen in the neurosurgical department of the clinic on Jan. 14, 1944, however, the patient had multiple complaints related to this episode. He complained of constipation, numbness in the region of the rectum and loss of sensation in the area of the scrotum and penis. Physical examination revealed an area of anesthesia over the fifth sacral nerve distribution in addition to a rather well defined area of obtunded sensation over the scrotum and penis. The rectal sphincter, although greatly relaxed, was functioning efficiently. Spinal fluid dynamics and an oxygen pneumospinogram were found to be within normal limits.

Case 10.—In October 1945 a white woman aged 61 had her gallbladder removed under continuous spinal anesthesia. A 5 per cent procaine hydrochloride solution dissolved in spinal fluid was used. A total of 125 mg. of this drug, administered in three divided doses, provided adequate anesthesia for the operation. At the time the spinal puncture was performed, however, the patient noticed severe paresthesia which extended down the leg into the plantar surface of the right foot. After the operation it was observed that the patient had a right foot drop, a loss of sensation below the right knee and an area of saddle anesthesia which was more pronounced on the right side.

When the patient was seen in the neurosurgical department of the Lahey Clinic sixteen months later, the complications previously described were still present in the right leg. The patient was found to have normal motor power in the quadriceps, adductor and abductor groups of the thigh muscles. She was also able to carry out a few degrees of plantar flexion of the right foot. The spinal fluid dynamics as well as an oxygen pneumospinogram was found to be within normal limits. It should be noted that this patient had a radical mastectomy five months before her cholecystectomy was performed, and the possibility of metastatic malignant growths cannot be overlooked as an etiologic factor in this complication.

Case 11.—In February 1945 a 58 year old white woman complaining of paralysis of the left leg of two years' duration was seen in the neurosurgical department of the clinic. This paralysis came on immediately after 150 mg. of procaine hydrochloride was given to provide spinal anesthesia for a hysterectomy. The patient experienced a sharp paresthesia down her left leg at the time the spinal puncture was performed. The operation was uneventful, and the return of motor and sensory function took place in a normal manner except in the left leg and sphincter vesicae. Voluntary control of urination was soon regained.

On examination two years later, there was complete loss of pain, temperature and tactile discrimination below the twelfth thoracic segment on the left side. All the muscles in the left leg were paralyzed except the quadriceps, abductor and adductor of the thigh. Although the patient could void voluntarily, 4 ounces (113 Gm.) of residual urine and persistent pyuria were present.

Cases Reported to Us by Other Surgeons and Anesthesiologists

Case 12.—A 30 year old white woman had been suffering from an apparent radiculitis with girdle pain which extended from her neck down to her lower abdomen. Two days before an operation for acute appendicitis was performed, lesions typical of chickenpox appeared on the body. A spinal anesthetic of 15 mg. of tetracaine hydrochloride and 1.5 cc. of 10 per cent dextrose was given for the appendectomy. The appendix was gangrenous but not ruptured, and the operation was uneventful.

The postoperative convalescence was normal for six hours, with the return of sensory and motor function in the extremities. This was followed, however, by complete paralysis, both motor and sensory, below the waist, with loss of bowel and bladder function. Associated with this, the patient complained of severe pain in the back, which the consulting neurologist interpreted as being due to radiculitis. Her recovery was gradual. First, the motor power, then sensation returned to the legs, and last of all the bowel and bladder function became normal. Seven weeks after the operation the patient left the hospital apparently fully recovered. It was thought that the paralysis was the result of myelitis caused by the chickenpox virus, with the spinal anesthesia acting as the exciting agent.

Case 13.—A 59 year old white man was given 10 mg. of tetracaine hydrochloride and 30 mg. of procaine hydrochloride for an anticipated rectal operation. The patient had a severe stabbing pain in the back at the site of the lumbar puncture; the pain came on as the anesthetic agent was injected. Sensation gradually diminished in the right leg and then in the left until the level of anesthesia reached the umbilicus. The operation was begun but had to be interrupted because of the severe pain which the patient experienced in his back. A week later he was still paralyzed below the waist and showed a loss of bowel and bladder control. A Pantopaque[26] spinogram was normal. The patient returned to his home where he showed gradual improvement. After three months his bowel and bladder functions were normal, and there had been some improvement in the motor power of the lower extremities. The severe pain persisted in his back. Five months after the onset of this complication, without apparent cause, he suddenly died. Permission for an autopsy could not be obtained.

Med. **229**: 6-14 (July 1) 1943.

[25] Munro, D.: The Rehabilitation of Patients Totally Paralyzed Below the Waist, with Special Reference to Making Them Ambulatory and Capable of Earning Their Living: I. Anterior Rhizotomy for Spastic Paraplegia, New England J. Med. **233**: 453-461, 1945; II. Control of Urination, ibid. **234**: 207-216, 1946.

The ampules containing the anesthetic agent had been soaked in a solution containing alcohol and formaldehyde, and the possibility that this corrosive mixture had leaked into one of these ampules and had ultimately been injected in the subarachnoid space was considered.

REGIMEN FOR THE PREVENTION OF POSTSPINAL NEUROLOGIC COMPLICATIONS

1. The cleansing and sterilizing of apparatus used in the administration of spinal anesthesia should be carefully supervised. The routine rinsing of syringes and needles with sterile isotonic solution of sodium chloride is an additional precaution.

2. Drugs should be used from manufacturers' ampules whose labels are legible, whose walls are intact and whose contents on routine inspection before use are clear and free from insoluble particles or crystals.[27]

3. Ampules containing spinal anesthetic drugs should be sterilized by soaking them in a nonirritating, colored sterilizing solution such as a 1 to 1,000 solution of high molecular benzalkonium chloride (Zephiran). The addition of a dye such as methylene blue to the solution in which ampules are immersed is of value in detecting the occasional defective ampule into which the sterilizing solution has leaked. Irritating solutions containing alcohol, phenol or formaldehyde should not be used because of the danger of their entering the ampule through microscopic breaks and in turn being injected into the subarachnoid space.

4. Solutions containing even a faint suggestion of turbidity or cloudiness should be discarded.

5. Spinal puncture should not be made through or near areas of infection.

6. Spinal anesthesia should not be given to patients with known spinal cord disease, such as tabes dorsalis, multiple sclerosis, pernicious anemia with symptoms of combined system disease and tumors of the spinal cord. Patients who have herniated intervertebral disks with signs of peripheral nerve paralyses, loss of bowel and bladder functions or an elevation in the total protein content of the spinal fluid should not be given spinal anesthetics.

7. Patients suffering from known virus infections such as poliomyelitis or chickenpox should not be given spinal anesthetics (for example, case 13).

8. A history of delayed return of motor function or severe paresthesias following a previous spinal anesthetic should be considered a contraindication to the subsequent use of this type of anesthesia.

9. If the spinal puncture causes a radiating paresthesia, the anesthetic agent should not be injected until adjustment of the needle has freed the patient of this pain (cases 10 and 11).

10. A persistently bloody spinal tap contraindicates the injection of a spinal anesthetic agent.

11. Routine determinations of the spinal fluid dynamics should be carried out on all patients complaining of intractable back pain or pain that seems out of proportion to the pathologic condition for which the surgical procedure is being performed. Experience has shown that spinal cord pathology (metastatic disease or primary carcinoma) can be detected in a certain number of these patients by such a routine. Hand[27] discovered 4 patients with a spinal fluid block by carrying out routine spinal fluid dynamics on a series of 60 patients whose intractable pain he was attempting to relieve by subarachnoid injections of ammonium sulfate. Cases 2 and 3 are examples of what can happen when a patient with spinal cord disease which is producing a spinal fluid block is given a spinal anesthetic.

12. When it has been difficult or impossible to obtain the desired height of anesthesia by the ordinary methods, a spinal fluid block should be suspected. It is advisable at the termination of such a spinal anesthesia to flush out the subarachnoid space with isotonic solution of sodium chloride to remove any residual anesthetic solution.

MANAGEMENT OF PATIENTS WITH CAUDA EQUINA SYNDROME FOLLOWING SPINAL ANESTHESIA

A patient who shows a delay in the return of motor and sensory function following spinal anesthesia should be considered for emergency treatment and immediate attention is warranted. Each step in the sequence of events leading up to the mishap demands careful investigation. A complete history and physical examination in addition to a review of the preanesthetic information should be obtained. The extent of the impairment of nerve function must be ascertained and recorded. It is of paramount importance that the functional state of the bowel and bladder be determined so that treatment, if needed, may be instituted immediately. Tidal irrigation of the bladder as described by Munro[24] offers a real chance for full recovery of function without infection of the urinary tract. It is extremely difficult to give an effective cleansing enema by ordinary measures to a patient whose rectal sphincter is incompetent. However, if a large Foley catheter is inserted into the

[26] Pantopaque, Eastman Kodak Company, is a mixture of ethyl esters of isomeric iodophenylundecylic acids.

[27] Crystals in solutions of tetracaine (Pontocaine) hydrochloride; personal communication from Dr. M. L. Tainter, Director of Research, Winthrop Chemical Company, Inc., Rensselaer, N. Y. Tetracaine hydrochloride, in common with all the synthetic local anesthetics of this general type, slowly hydrolyzes in water to produce 4-N-butylaminobenzoic acid.

This compound is 0.0087 per cent soluble in water at the p_H of tetracaine hydrochloride solutions (3.5 ± 0.5) at room temperature. It is freely soluble in the presence of traces of alkali. When the degradation of the tetracaine has proceeded to a point where the solution is supersaturated with respect to this new compound, then crystals gradually develop. The time required for this is dependent on temperature, the concentration of the solution and other more variable factors. A solution containing such crystals obviously should not be used. Nevertheless, since an occasional crystal might be inadvertently injected, it is desirable to know whether these crystals might exert any untoward effects. Dr. Tainter made a solution of these crystals by dissolving them in the required amounts of alkali and injected 300 mg. per kilogram of body weight intravenously in rats without untoward result. Tetracaine hydrohloride has an $L.D._{50}$ (dosage lethal to 50 per cent of the rats) of 6.0 ± 0.5 mg. per kilogram of body weight under the same conditions. Instillation of a suspension of the crystals into the conjunctival sac of rabbits produced no anesthetic effect in 5 out of 6 rabbits. A 1 per cent solution of butylaminobenzoic acid was injected into the subarachnoid space of rabbits in volumes of 0.02 cc. per centimeter of spinal length, which is the standard quantity used in the study of spinal anesthetics for this particular species of animal. Anesthesia did not result. One half of the animals were killed after forty-eight hours and the other half after ninety-six hours. There was no evidence of hyperemia or other inflammatory changes in any of the animals.

From these experiments Dr. Tainter concluded that the butylaminobenzoic acid sometimes found in tetracaine hydrochloride solutions as a crystalline precipitate is an inactive compound when injected intravenously or intrathecally in experimental animals.

rectum and the cuff inflated, an effective enema can be administered.

In order that preexisting pathologic change in the spinal cord may be discovered, any patient in whom there develops a postspinal cauda equinal complication should have an investigation of his spinal fluid dynamics. In conjunction with this maneuver, it is advisable to irrigate the subarachnoid space with isotonic solution of sodium chloride to insure the removal of any remaining anesthetic agent. This attempt to remove any residual anesthetic agent takes on additional significance when a spinal fluid block is discovered. When the abnormal observations in the spinal fluid are limited to an elevation in the total protein and in the lymphocytic cell count, daily spinal punctures for the withdrawal of fluid should be performed.

During the period of recovery, the duration of which may be extremely variable, the nursing routine must be a vigorous one if decubital ulcerations, ankylosed joints, malnutrition and muscular atrophy are to be avoided.

Certain of these complicated cases may require special and intensive treatment before the patient can be rehabilitated. Especially is this true of those patients who suffer from uncontrolled urination or those in whom there has developed a spastic paraplegia with mass reflexes. If tidal irrigation is properly applied over a sufficiently long period, Munro[25] has stated that: "Every patient who has sustained an injury to the spinal cord, conus or cauda equina who is intelligent and cooperative can have infallible twenty-four-hour control of urination." Munro[25] has also shown that patients paralyzed below the waist can be made ambulatory and capable of earning a living. He advocates anterior rhizotomy for the relief of the spasticity. Then, by the use of braces and crutches, these people can be made ambulatory.

ABSTRACT OF DISCUSSION

DR. J. ARCHER O'REILLY, St. Louis: I feel that a spinal puncture or the giving of spinal anesthesia should be considered a major surgical procedure. I think, sometimes, that fact is overlooked. In the St. Louis University group of hospitals it is required that a trained medical anesthetist shall give all spinal anesthesias and supervise them. For that reason we probably have comparatively few complications. In reviewing the cases that have been treated by the orthopedic service—and a good many patients have had spinal anesthesias under other men—I cannot find any very serious complications. We have had headaches, but I cannot think of any serious paralysis or any other complications. Again I think that is probably due to the fact that we insist on having trained men. I feel that from this paper there is a definite lesson to be learned. Complications are fairly frequent. Some of the complications are very serious. One of the things we must learn is that the surgeon must know his patient. The surgeon who uses spinal anesthesia to any great extent should have enough experience and should be able to evaluate the patient and be able to understand the possibilities of complication before he jumps into a spinal anesthesia. That is a serious and vital responsibility on the part of the operating surgeon. What I get from this paper is the fact that spinal anesthesias may cause considerable damage. The point that is especially important is the fact that spinal anesthesias should be given by men who are competent and should be under the supervision of surgeons who know what spinal anesthesia is and may do and that it should not be entered into lightly.

DR. A. M. CAINE, New Orleans: I want to emphasize something said; that is, the coloring of the solution in which the ampules are kept. I had two sloughs in the skin from the administration of a small portion of 1 per cent procaine with ephedrine. I could not think of any reason why that took place, and since I could not think of any other reason I put my ampules in a colored solution, since which time I have found a dozen that were colored. There is no reason at all why, in using solutions of procaine that are made instead of crystals—or pontocaine or nupercaine, or any other agent—one should not get some alcohol in these solutions unless they are put up in a container with a colored solution, so that one can find out. I have thought that a good many complications might be due to the size of the needle until I found out the size of the needle that the neurologists use in spinal puncture, which is a very large needle indeed. They have many headaches, and they expect them. I think the size of the needle may have something to do with the headaches. But from what Drs. Nicholson and Eversole say practically no neurologic complications have been reported by them. But I know of 1 case in which, when the anesthetist pulled the stilet out, blood came trickling out. She put it back half an inch and put it into the spinal canal. That particular operation was for abdominal anal resection. No complication had been reported to me or to our anesthetist. The patient reported to me ten months later that his whole bottom had been dead ever since the operation. I feel that in this case it was due to a hematoma resulting from the original puncture, which went all the way through and a half inch back before the anesthetist got back into the subarachnoid space.

CAPTAIN JOHN DILLON, M. C., A. U. S.: It is absolutely necessary that studies of anesthetic complications be made. However, there is one thing that has not been brought out. That is the relationship of these complications to the drug, the amount of the drug and the hypobaricity or the hyperbaricity of the drug. These things are very important. I cannot speak from personal experience or give any data on this topic, but if the subject is to be worked out so that these complications will be cut down to a minimum some thought must be given to these factors, particularly to the hyperbaricity. We are not at all certain as to how spinal anesthesia works, or at all sure how any anesthesia works, for that matter, but it would seem that there must be some surface phenomenon which goes on between the nervous tissue and the drug which is opposed to it, and that the osmotic relationship between these two surfaces come into play. As Dr. Betlach brought out, you can get perfect anesthesia with 35 mg. of spinal anesthesia. I wish to go further and say that I have seen it as low as 12.5 mg. I wonder sometimes if we are not hitting a tack with a sledge hammer, because in years gone by it was nothing to read that a patient had been given 300 mg. of procaine for operations that certainly did not require it.

DR. URBAN H. EVERSOLE, Boston: As Dr. O'Reilly pointed out, the incidence of neurologic complications following spinal anesthesia is very low. In our own experience we gave approximately 21,000 anesthetics by the same technic before we had a serious neurologic complication. On the other hand, this low incidence must not lead us to minimize the gravity of such a complication. I certainly agree with Dr. Dillon that it is important to consider these complications in relation to the specific gravity of the anesthetic mixture employed. There is little doubt that neurologic complications following spinal anesthesia bear a definite relationship to the concentration of the drug. Clinical evidence of this is that most of these complications are in the cauda equina, where the drug is most likely to be present in the highest concentration. We know that the concentration of an anesthetic agent at any given point in the spinal canal has a very definite relationship to the specific gravity of the solution employed. As mentioned in the paper, the concentration commonly employed for spinal anesthesia may be but little short of that which would cause neurologic complications in a much greater number of patients.

SUBDURAL HEMATOMA

HAROLD C. VORIS, M.D.
Chicago

This report is based on the observations in 100 consecutive patients with subdural hematoma on whom I have operated. This group of cases is large enough to be somewhat heterogeneous but has many common features. Cases of infantile subdural hematoma have not been included. The majority (73) of the patients are from my neurosurgical service at the Cook County Hospital, the rest (27) from my private practice. They represent an eleven year period, from 1935 to 1945 inclusive. Hematomas less than 3 mm. in thickness or an estimated 10 cc. in volume are not included.

The subject of subdural hematoma has aroused great interest in the past, and an extensive literature has accumulated. Groff and Grant[1] prepared an excellent collective review in 1942 in summary of the literature to that date. They classified the causes under the headings "spontaneous" and "traumatic." Under each of these headings primary and secondary causes were listed. Primary spontaneous causes were infectious and neoplastic; secondary spontaneous causes were the predisposing factors of systemic disease, alcoholism, arteriosclerosis and blood dyscrasias. Trauma was described as a primary cause and also as a secondary or precipitating cause in the presence of one of the predisposing factors listed under spontaneous causes.

PATHOGENESIS

In the recent literature the trend has been to consider trauma as the most important etiologic factor. The normal anatomy of the cerebral veins has long been recognized as important in the production of subdural hemorrhage. The term "bridging veins" may be applied to the veins that cross the subdural space to the dural venous sinuses and also to the veins that cross the subdural space traveling between the arachnoid and dura but emptying directly into any sinus. The first group includes the superior cerebral veins, the inferior cerebral veins that enter the sphenoparietal sinus and the veins that enter the lateral sinus from the posterior or inferior surface of the temporal lobe. Other veins cross from the cerebral arachnoid of the convexity of the hemisphere to the dura at a distance of 1 to 4 cm. from the superior longitudinal sinus, traverse the subdural space from the arachnoid of the base of the temporal lobe to the dura of the middle fossa and to the tentorium cerebelli, cross from the tip of the temporal lobe to the dura over the sphenoid bone, or enter the dura from the lateral convexity of the hemisphere at any point. All these veins are familiar to the neurosurgeon because they limit his manipulations when he explores the subdural space.

It is obvious that displacement of the brain in the intracranial cavity, especially in the longitudinal axis, may tear these veins as they cross the subdural space and may produce primary subdural hemorrhage. Beginning with Trotter[2] many authors have recognized this as the probable initial step in the production of a subdural hematoma. However, experimental proof of this has been lacking until Sheldon, Pudenz and Restarski[3] demonstrated experimentally subdural ("sublucite") venous bleeding following parietal subconcussive blows in monkeys in whom the convex portion of the skull had been replaced by a transparent Lucite calvarium. This experimental demonstration supports the clinical supposition that an initial hemorrhage into the subdural space is the first stage in the development of a subdural hematoma. Such hemorrhage is most apt to occur from superior cerebral veins but often occurs from other groups, so that while the majority of traumatic subdural hematomas occur over the convexity of the cerebral hemisphere they are found inferiorly in the temporal region both anteriorly and posteriorly, occasionally beneath the frontal and temporal lobes and even in bizarre locations, such as between the hemispheres (Aring and Evans[4]) or beneath the tentorium cerebelli (Munro[5]).

In the present series trauma was by far the most important factor, as a definite history of antecedent injury to the head was obtained in 96 of the cases. The time between the injury and the operation ranged from a few hours to six months. Injuries which dated back more than six months from the time the patient was first seen were not accepted as possible causes; in fact, any injury which occurred more than three months before the onset of symptoms was regarded with suspicion. There were only 2 such cases in the series.

In the great majority of instances the clots were located over the superior convexity of the hemisphere. Some were more lateral and inferior, extending down to the base. None was truly beneath the hemispheres, and there were no subtentorial hematomas in this series.

Although trauma was the primary causative factor in the vast majority of the cases, there were a few patients with other preexisting cerebral lesions that obviously predisposed to the subdural hemorrhage.

Neoplasm has frequently been mentioned as a predisposing factor. Russell and Cairns[6] reported 4 cases of carcinomatosis and sarcomatosis of the dura with formation of a subdural false membrane. In 1 patient in this series a subdural hematoma was found over a glioblastoma multiforme of the temporal lobe.

A 45 year old man was struck on the forehead by a heavy object and knocked down. He was dazed but did not lose consciousness. After this incident headaches persisted, and two months later disorientation and mental confusion appeared. Six months after the injury right hemiparesis and aphasia developed and he was admitted to the Cook County Hospital, eight months after the injury. At the time of admission he was stuporous, with complete right hemiplegia and aphasia and bilateral papilledema of 2 to 3 D. The pressure of the spinal fluid was 210 mm., and the fluid was xanthochromic. Because of the history of injury, a subdural hematoma was suspected, although the interval seemed rather long. Bilateral parietal bur holes did not confirm the suspicion. Ventriculography revealed a space-occupying lesion in the left frontotemporal region. An osteoplastic craniotomy revealed a small completely organized subdural hematoma in the left anterior temporal region. The membranes of this hematoma were completely fused with organization of the contents. The hematoma was only 3 mm. thick. Beneath it a glioblastoma multiforme came to the surface of the anterior part of the temporal lobe.

From the Clinics of Mercy Hospital and Loyola University and from the Cook County Hospital.

Read before the Section on Nervous and Mental Diseases at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

In another patient a subdural hematoma lay over a vascular malformation of the temporal lobe.

A 28 year old man, a teacher, had been struck over the head two months before I saw him. He had a headache for a few hours but had not lost consciousness and thought that his injury was inconsequential. A month later he began to have seizures involving the upper part of the right arm and the right side of the face without loss of consciousness but with inability to speak during the seizure. The tendon reflexes were exaggerated on the right, there was a right Hoffmann sign and bilateral papilledema of 1 to 2 D. The injury was considered inconsequential and a diagnosis of left cerebral tumor was made. Osteoplastic exploration revealed a chronic encapsulated subdural hematoma over the left frontoparietotemporal region with its greatest thickness over the temporal lobe. It was removed *in toto* and measured 7.4 by 4.5 by 1 cm. Its removal revealed an arteriovenous anomaly of the entire temporal lobe. The sylvian vein was 1 cm. in diameter, and two pencil-sized vessels connected it with the superior longitudinal sinus. These vessels pulsated and obviously carried a mixture of arterial and venous blood. The surface of the temporal lobe was replaced by a pulsating mass of vessels of various sizes. Surgical attack was not attempted because of the location of the lesion on the left side and the obvious immediate danger of such a procedure.

A third subdural hematoma was found in the course of a surgical attack on an intracranial aneurysm.

A 37 year old woman was first seen twelve hours after a severe spontaneous subarachnoid hemorrhage. At that time she was comatose, with a left hemiplegia and a complete right oculomotor palsy. She gradually improved, and six weeks later a cerebral arteriogram revealed a small berry aneurysm of the right anterior cerebral artery about 5 mm. from its origin. A right transfrontal craniotomy was performed, and the right anterior cerebral artery was occluded with a clip proximal to the aneurysm. At this exploration a small, 1 mm. thick, completely organized subdural hematoma was found over the inferolateral aspect of the right temporal lobe.

These 3 cases are of great interest, although they represent only a small fraction of the series. In all 3 instances the arachnoid must have been torn; in the first 2, possibly by trauma, and in the third, perhaps by the force of the hemorrhage. Blood thus entered the subdural space and, possibly because of a ball-valve action of the tear in the arachnoid, remained entrapped in the subdural space. All 3 cases may represent spontaneous hemorrhage; certainly the third does. However, there was a definite history of trauma in the first 2.

The relation of acute and chronic subdural hematoma is a debated point. Groff and Grant suggested the use of the term subdural hemorrhage for the early acute cases and subdural hematoma for the later subacute or chronic cases. Leary[7] classified subdural hematomas under five heads: (1) fresh fluid or soft clots, (2) firm clots, (3) chocolate-colored fluid with a neomembrane on the dural side, (4) chocolate-colored fluid enclosed in a double neomembrane and (5) a fused double subdural neomembrane with absorption or complete fibrous organization of the previously enclosed hematoma.

The important difference between the acute and chronic types is the relative size of the early hemorrhage. Generally the so-called early or acute subdural hematoma is a relatively massive, acute hemorrhage, usually associated with severe cerebral injury, either contusion or laceration. Probably as a rule, the arachnoid is extensively torn and the subdural blood is in free communication with the subarachnoid space. If the patient survives the injury to the brain and the early effects of the cerebral compression, the subdural hemorrhage is absorbed by virtue of its communication into the subarachnoid space. This does not always occur, but seldom do severe cases of injury to the brain later exhibit a chronic hematoma. Such a case is seen infrequently; perhaps here the tear in the arachnoid is small and acts as a ball valve to trap the blood in the subdural space.

Blood trapped in the subdural space is not absorbed. Gardner,[8] Zollinger and Gross[9] and Munro and Merritt[10] developed the now widely accepted theory that the large chronic subdural hematomas result from relatively small initial hemorrhages in the subdural space. In the absence of cerebral injury with bleeding from cortical vessels, the venous pressure in the cerebral veins is so low that bleeding from them soon stops spontaneously. As liquefaction of blood in the subdural space begins, the resultant fluid is high in protein content. Since it is separated from the subarachnoid space by only the arachnoid (and much later by the newly developing neomembrane on the arachnoid side) and since this is impermeable to the large molecules of protein in the liquefying blood, an osmotic imbalance which exists between the cerebrospinal fluid and the liquefying blood in the subdural space results in the passage of fluid into the subdural space. As time goes on and the hemoglobin molecules begin to break down, there is a great secondary increase in molecular concentration following the break-up of the large protein molecules; consequently, there is a late secondary tendency to an increase in the size of the clot.

Many surgeons have felt that repeated hemorrhages were the explanation for the growth of the clot. Certainly when the initial hemorrhage is spontaneous or when a predisposing cause is present there may be successively repeated hemorrhages. Putman,[11] Baker[12] and others have described microscopic evidence of fresh bleeding in the vessels of the membranes of subdural hematomas. However, gross evidence of such bleeding is lacking. None of the hematomas in this series, whatever their age or stage, show lamellation or other evidence of repeated bleeding. In 1 or 2 cases, when the clot was removed fresh bleeding appeared from torn but previously thrombosed veins, but evidence of recent bleeding into the hematoma was not seen. In 1 case, after evacuation of the hematoma the exposed end of a torn but thrombosed cerebral vein was seen above the arachnoid directly beneath the exploratory opening in the parietal region. When the vessel was lightly sponged it began to bleed and required electrocoagulation. The hematoma was thickest over this point and from the history was five days old. It was thought to have been due to a tear of this anomalous "bridging vein" on the parietal convexity of the hemisphere. Loss of blood from this vessel had spontaneously stopped only to recommence after evacuation of the overlying hematoma and the slight trauma of sponging.

An essential question is the primary location of the bleeding, whether subdural or intradural. If it is due to tear of bridging veins, the bleeding must of course be subdural. However, Baker,[12] Hannah,[13] Kamp and Love [14] and others have presented histologic evidence to indicate the intradural origin of these hemorrhages. The most satisfactory histologic preparations come from postmortem rather than from surgical specimens. As a result, the average pathologist is better acquainted with material from large, well encapsulated hematomas of relatively long standing. Leary,[15] who had an enormous experience with subdural hematomas in all stages of their development, was convinced of their subdural rather than intradural origin.

[12] Baker, A. B.: Subdural Hematoma, Arch. Path. **26:** 535-559 (Aug.) 1938.

From the surgical point of view three facts can be emphasized:

1. Early traumatic subdural hematomas are not encapsulated, and the inner aspect of the dura lacks evidence of reaction.

2. The first neomembrane to be formed is the one on the dural side, and it is well developed before any definite membrane can be found on the arachnoid side.

3. *Only in old cases are there two neomembranes* equal in development on the dural and arachnoid sides of the hematoma. The early development of the neomembrane on the dural side is to be expected if the initial hemorrhage is subdural, because reaction to a foreign body is much more prompt and more pronounced in the dura than in the arachnoid. If the hemorrhages were really intradural and the inner (arachnoid side) neomembrane represented the inner layer of the dura, it should be present from the onset. At operation the dura always separates readily from the neomembrane of the hematoma. In early cases the inner surface of the dura appears grossly normal; in older cases the dura may appear thickened, with the inner surface roughened and discolored.

Groff and Grant [1] supported the intradural theory *by pointing out the tendency of these hemorrhages to* predominate over the superior convexity of the hemisphere. They stated that this collection of blood and fluid over the superior convexity of the hemisphere defied gravity and favored an intradural rather than a subdural location. However, the living brain behaves physically as a semisolid. When the dura is opened at operation in the absence of increased pressure the brain falls away from the dura and settles down into the intracranial cavity. It probably does the same thing when bleeding occurs into the subdural space over the convexity of the hemisphere, thus preventing the blood from settling to the base. According to Munro and Merritt [10] the age of a subdural hematoma can be rather accurately determined by microscopic study of the neomembranes and total protein determinations of the fluid removed at operation. I have not been able consistently to correlate these factors with the known histories of injury. The 2 following cases illustrate the difficulty in such correlation.

A 30 year old man fell and struck the back of his head six weeks before admission to the hospital. Headache had been present since the fall, and his family and the patient (later) were certain there had not been any other injury. He was stuporous, with bilateral papilledema and left hemiparesis. At operation a large semisolid subdural clot was found in the left parietotemporal region without evidence of liquefaction, neomembrane formation or dural reaction. Grossly, it appeared to be of recent origin, at most a few days old.

A 31 year old man received a blow to his head two hours before admission to the hospital. He was stuporous at admission, and he fluctuated between semicoma and periods of relative responsiveness and confusion during the next five days. *Left hemiparesis developed. The spinal fluid pressure* was 110 mm. and the fluid was xanthochromic. Surgical intervention revealed a right subdural hematoma that was largely liquefied, although partially organized fragments of clot were evacuated. A well formed neomembrane was present on the dural side and a definite but less well developed neomembrane next to the arachnoid.

These 2 cases stand in decided contrast to each other and illustrate the variability between the age and the stage of the development of the hematoma. These variations are probably due to differences in the size of the initial hemorrhage, to whether or not the arachnoid is injured and to individual variations in the reaction of the dura to blood in the subdural space.

The relation of subdural hygroma to subdural hematoma must be considered. Many have considered this *lesion to be a variant of subdural hematoma, representing* cases of an extremely limited initial subdural hemorrhage which eventually as a result of great dilution by osmosis became only xanthochromic fluid. The protein content of these fluids is surprisingly high, although they do not coagulate when removed. In 1 case the fluid removed at operation contained 2,000 mg. of total protein. Da Costa and Adson [16] considered subdural hygroma to be a separate clinical entity. They reported a case in which a tear in the arachnoid was demonstrated at operation. It had apparently not only allowed cerebrospinal fluid to enter the subdural space but also acted as a valve to prevent its return to the subarachnoid space.

In the present series there were 9 cases classified as subdural hygroma. Six of these were from two to *six weeks old; the other three, a week or less.* It appears that the first group might well represent the end stage of dilution of an exceedingly small subdural hemorrhage. In all these cases there were well developed neomembranes. The 3 recent cases lacked neomembranes, and it is likely that they were formed by the mechanism demonstrated by Da Costa and Adson.[16] In all 3 cases there was an associated contusion or laceration of the brain. Subarachnoid hemorrhage with consequent admixture of blood with the spinal fluid would account for the xanthochromia. Unfortunately, total protein determination was not performed in these cases. Scott [17] reported a case of acute subdural hygroma which consisted of clear fluid with a simulation of extradural hemorrhage. It seems that adequate proof of a subdural hygroma should consist of demonstration of (1) *a tear in the arachnoid,* (2) xanthochromic fluid or (3) high protein content in the fluid.

SYMPTOMS AND DIAGNOSIS

Men and women are probably equally susceptible to subdural hematomas, but as a result of the greater frequency of head injury in males such injuries are much more common in that sex (table 1). Subdural hematoma occurs at any age but is rare between infancy and young adulthood. The fourth, fifth and sixth decades of life provide the most cases. As in head injury generally (Voris, 1945 [18]), the increasing age of the patient is an important factor in the determination of mortality. In a previous paper (Voris, 1941[19]) the common signs and symptoms of subdural hematoma have been discussed. Experience with a larger group of cases has changed my opinion in regard to the relative frequency of some of the signs and symptoms; it has not otherwise altered the opinions I expressed in 1941.

The differentiation between acute and chronic forms of subdural hematoma is important not only from the standpoint of pathogenesis but also from that of treatment and prognosis. The most convenient classification from a clinical point of view is on the basis of elapsed time between the injury and the operation on the patient (table 2). That the elapsed time was between injury and surgical intervention, not between injury and the onset of symptoms should be kept in mind. In many of the older cases symptoms such as headache, dizziness or mental disturbance had been present for some time before surgical intervention, perhaps even from the time of injury.

The high mortality in acute subdural hematoma is seen at a glance. It is prohibitive for the very early cases and extremely high during the first week. Ten cases in which the operation was performed within three days after the injury was sustained were reported in 1941; in only 4 additional cases have acute subdural hematomas been operated on since, and those under the diagnosis of extradural hemorrhage.

TABLE 1.—*Distribution of Patients by Age and Sex with Mortality Rate for Each Decade*

	Total	10-20	20-30	30-40	40-50	50-60	60-70	70+	?
Males	88	1	10	16	27	17	13	1	3
Females	12	..	1	5	2	1	3	..	..
Recovered	70	1	10	16	21	15	7	..	..
Dead	30	..	1	5	8	3	9	1	3

The clinical differentiation between acute subdural and extradural hemorrhage is often difficult, if not impossible. The early subdural hemorrhages are generally massive; they are always associated with cerebral injury and often with laceration. The bleeding is usually venous but may be arterial from torn cortical vessels. As previously indicated, since 1941 I have operated on these patients only in the course of explorations for extradural hemorrhage. The acute subdural hemorrhage it is well to leave alone. If the patient survives, the hemorrhage is perhaps often absorbed through tears in the arachnoid. As previously stated, chronic subdural hematoma is not often seen in patients with severe early symptoms after injury to the head.

The clinical course of chronic subdural hematoma is of two general types. In the first, subjective symptoms are present from the time of a mild or moderately severe head injury. These cases predominate in this series. In the majority, the relationship of the injury to the symptoms is evident; the only question is the existence of a subdural hematoma.

In another group of patients, the injury was trivial, has been forgotten, or is not known to friends or relatives. These patients are suspected of having a brain tumor, cerebral vascular disease, an encephalopathy or encephalitis. If mental symptoms predominate, the diagnosis of one of the psychoses may be made. If the patient is admitted to the hospital in coma, uremia or diabetes may be suspected. In this instance the value of spinal puncture in the differential diagnosis of coma should be emphasized. Fluctuation of symptoms, especially of the state of consciousness, is often seen and is at times dramatic.

A 66 year old man was seen late at night in consultation. He was deeply comatose, with generalized rigidity of the extremities, Cheyne-Stokes respirations and a rectal temperature of 105 F. The spinal fluid was said to have been clear but under increased pressure. The optic fundi were not elevated. He was thought to be moribund, but the administration of 100 cc. of 50 per cent sucrose intravenously was advised and a ventriculogram was planned for the next morning if he survived. By morning (eight hours later) he was conscious, alert and asking for food. His family refused to permit a surgical procedure at that time. A history of slight injury to the head five weeks previously was obtained. The diagnosis was changed from a suspicion of brain tumor to subdural hematoma, and relapse was predicted. Three days later the patient lapsed again into coma. The family readily consented to an operation, which revealed bilateral, large, fairly well encapsulated, liquid, subdural hematomas. Recovery was uneventful.

TABLE 2.—*Classification of Patients, with Mortality According to the Period from Injury to Operation*

	1-3 Days	3-7 Days	1-4 Wks.	1 Mo. or More	No History of Injury
Total	14	9	47	26	4
Recovered	1	3	40	22	4
Dead	13	6	7	4	..

Some type of mental disturbance ranging from a mild personality change to stupor or coma was the most common observation (table 3). The mental picture may fluctuate greatly but grows worse with the passage of time. Confusion and disorientation which progress to stupor and coma are the most commonly observed manifestations. Simulation of one of the organized psychoses is infrequent but occasionally occurs.

Weakness or paralysis of one side of the body with abnormal or pathologic reflexes is usually contralateral to the hematoma; occasionally the contralateral crus cerebri is pressed against the free edge of the incisura tentorii, and hemiparesis and pyramidal tract signs are thus produced homolateral to the clot. Some type of localizing neurologic observations were present in 75 cases; contralateral to the lesion, in 63; homolateral, in 12. The presence of hemiparesis or signs of unilateral involvement of the pyramidal tracts after a head injury, especially if progressive, is strong presumptive evidence of a hematoma, but these results may be produced by localized injury to the brain.

TABLE 3.—*Signs and Symptoms in One Hundred Surgically Verified Cases of Subdural Hematoma*

Mental disturbances		90	Papilledema		37
Localizing pyramidal signs		75	Convulsions		29
Contralateral	63				
Homolateral	12		Slow pulse		29
Headache		62	Spinal fluid examination		85
			Bloody	14	
Dilatation of pupil		45	Xanthrochromic	55	
Contralateral	5		Clear	16	
Homolateral	40				

Headache, as might be expected, was a common symptom, which occurred in 62 cases. Unilateral dilatation of the pupil occurred in 45 patients. It was homolateral to the lesion in 40 and contralateral in 5. It is thus not only a valuable symptom of a developing

---

19. Voris, H. C.: The Diagnosis and Treatment of Subdural Hematomas, Surgery **10**: 447-456, 1941.

hematoma but also a valuable localizing sign. When the dilatation is contralateral to the hematoma the possibility exists of injury to the brain on the side of the dilated pupil.

Papilledema was present in 37 patients. As might be expected, these were all patients who had injuries of five days' duration or longer. I have not seen papilledema earlier than five days after injury.

Convulsions were seen in 29 cases. This is about the frequency generally reported for neoplasm of the cerebral hemisphere. When they occur unilaterally, convulsions are of great localizing value. When they occur after a cerebral injury, they strongly suggest a subdural hematoma, although they may be the result of localized cerebral contusion or edema.

Occasional bradycardia with a pulse rate below 60 was seen in 29 cases. It is seldom persistent but does tend to be recurrent. It is usually observed only by review of the hospital chart over a period of several days; consequently it is easily, and undoubtedly often, overlooked in patients who have been in the hospital only a short time before surgical intervention.

Examination of the spinal fluid was carried out in 85 cases. It was bloody in 14 (all within fourteen days after injury). In 55 patients (65 per cent) it was xanthochromic; in 16, clear. Aside from the early cases of patients with bloody spinal fluid, xanthochromia was found in 77 per cent of those examined. Clear spinal fluid does not rule out, or even make unlikely, the presence of a subdural hematoma, but xanthochromic spinal fluid usually indicates the diagnosis. However, if there is less than two weeks' time between the injury and the examination of the spinal fluid, the xanthochromia has to be disregarded, since it may be the result of subarachnoid hemorrhage suffered at the time of the injury. Observation of the data on the spinal fluid in a large number of cases of traumatic subarachnoid hemorrhage indicates that the spinal fluid will be clear within twelve to fourteen days after a cerebral injury unless there is a developing subdural hematoma.

Most important of all in the diagnosis of subdural hematoma is the alertness of the clinician. This alertness must include the realization not only that subdural hematoma is one of the most frequent surgical complications of head injury but also that any patient with the signs and symptoms of cerebral disease may have this condition. It is especially to be considered in "stroke" or "mental disease" or when the patient is in coma. The manifestations are protean, and there is no constant factor short of surgical exploration that will definitely establish the diagnosis.

The value of air studies is debatable. Davidoff and Dyke[20] were of the opinion that the encephalogram (spinal air) is of diagnostic importance. Others (e. g. Bull[21]) have emphasized the difficulties of diagnosis by means of air studies. The procedure of ventriculography has often led directly to the correct diagnosis, for when the surgeon made bur holes in the skull for the injection of air, the presence of the subdural hematoma was recognized. This occurred in 1 case in this series.

A 15 year old boy had been "knocked out" while boxing two months previously. A month later headaches, dizziness and vomiting began. Examination revealed ataxia, papilledema and right lateral rectus paresis. A suboccipital tumor was suspected because of the youth of the patient, the ataxia and the lack of lateralizing signs, and ventriculography was advised. When a bur hole was placed in each parietooccipital region, a liquid subdural hematoma of moderate size with well developed neomembranes was revealed on the left side. It was satisfactorily drained, and recovery was uneventful.

A case has already been described in which a small, anterior, organized subdural clot was not revealed by a parietal bur hole and, consequently, ventriculography was performed. In another case ventriculography was performed because of suspicion of a brain tumor. This yielded evidence of a right frontal space-occupying lesion. Craniotomy revealed a small, chronic, subdural hematoma over the right frontal lobe. This patient later recalled several minor head injuries in the preceding six months. In 3 other cases in which a tumor of the brain was suspected, encephalography was performed and revealed evidence of a space-occupying lesion. Craniotomy revealed the true nature of the lesion in 2 of these cases; in the third, the hematoma was drained in the usual way through a parietal bur hole.

TREATMENT

Trotter,[2] who was the first modern surgeon to interest himself in this condition, used trephine openings to evacuate the clots. This procedure seemed to be forgotten and osteoplastic craniotomy was generally employed until Fleming and Jones[22] and McKenzie[23] independently advised, in 1932, simple drainage through bur holes. This method was used in all but 8 cases in this series. In 4 of these cases, the method was used after the air studies to which reference has been made. One case already described was an instance of intracranial aneurysm. Here the small subdural hematoma was an incidental discovery. In another patient who failed to rally after drainage of a large, well-encapsulated clot, an osteoplastic craniotomy was carried out nine days later and the entire neomembrane meticulously removed. In spite of this, death occurred two days later. It was felt that this death was due to a failure of the brain to expand after removal of the hematoma. In another case osteoplastic craniotomy was necessary to remove a completely organized clot that was 2 cm. thick. Here the neomembranes were fused and the interior of the mass completely organized. This occurs rarely; such clots cannot of course be evacuated through bur holes. In the eighth case a parietal bur hole revealed the edge of a solid, unencapsulated clot in the inferior temporal region. This might have been evacuated through multiple bur holes but was removed through an osteoplastic craniotomy.

It is my practice to place these patients flat on their back with the head of the table elevated 10 to 15 degrees. The entire head is shaved and after surgical preparation is draped so as to expose practically the entire convexity of the skull. The operation can generally be done under local anesthesia, but if the patient is too restless or uncooperative for this, intravenous Sodium Pentothal or a preliminary dose of tribromoethanol may be used as a basal anesthetic.

Vertical incisions 4 cm. in length are made on each side of the scalp above the lobe of the ear and just above the insertion of the temporal muscles. Scalp clips or forceps on the galea control the hemorrhage of the scalp and small self-retaining retractors expose the bone. Bur holes are then made just above the insertion of the temporal muscle on each side. If the dura is discolored, the bur hole may be enlarged with the rongeur to an opening approximately 3 cm. in diameter. This gives more room for manipulations. Almost always the appearance of the dura reveals the underlying hematoma, if one is present. The underlying blood gives the dura a characteristic plum-colored appearance. A bur hole in this location will reveal the lesion in the vast majority of subdural hematomas. The lesion of necessity assumes the shape of a convex lens spread out over the surface of the hemisphere but thickest at the point of origin. If a hematoma is not disclosed on either side, additional bur holes may be made in the frontal and inferior temporal region, or ventriculography may be performed. It seems less time-consuming to depend on ventriculography rather than on multiple bur holes for the recognition of small or aberrantly located clots.

[23] McKenzie, K. G.: A Surgical and Clinical Study of Nine Cases of Chronic Subdural Hematoma, Canad. M. A. J. 26: 534-544, 1932.

Even when a clot is disclosed on the side first explored, a bur hole should be made on the opposite side. Fourteen patients in this series had bilateral hematomas. When a hematoma is not found on the side first explored, then the other side must always be explored. Reference has already been made to the frequency of false localizing signs. In this series homolateral hemiparesis or pyramidal tract signs occurred in 17 per cent of the total number of cases with such neurologic signs. Failure to explore the second side, resulted in overlooking the hematoma in 1 case in this series. Necropsy two days later revealed the clot. This patient had a homolateral hemiparesis, and the case was one of those encountered early in my experience.

After the dura is opened evacuation of the hematoma is readily accomplished in most cases. With the head postured as described, most of the liquid hematomas will escape by gravity as soon as the dura is opened and the neomembrane of the hematoma is ruptured. If the clot is solid or semisolid, simple alternate irrigation with isotonic solution of sodium chloride and suction through a catheter passed beneath the dura will serve to break it up. Irrigation with isotonic solution of sodium chloride must be resorted to cautiously or not at all in acute cases because it induces swelling of the brain, which is often already present. In the chronic cases there is often difficulty in getting the brain to expand, and repeated irrigations appear to be of value in attaining that objective.

Occasionally the primary bur hole is at the edge of the clot, or difficulty is experienced in breaking up a relatively solid clot. Should this occur, additional bur holes may be placed over the center of the now localized clot or at its other edge, and through and through irrigation used. This was done in 2 cases. As already mentioned in 2 other cases, an osteoplastic craniotomy was used to evacuate an organized or solid clot.

In older persons, and especially in patients who come to the surgeon late, one occasionally finds that the cerebral hemisphere does not expand to fill the space formerly occupied by the clot. Trotter[2] noted this in the 2 fatalities that he reported. Both Grant[24] and Coleman[25] in 1935 called attention to the grave prognostic value of this observation. Cohen[26] reported a remarkable and much quoted case of this type in which the patient finally recovered after repeated aspirations of the subdural space. In my experience these cases all terminated fatally, in spite of drainage of the subdural space and the intravenous administration of hypertonic fluids in an attempt to swell the brain. Munro[5] quoted Henschen as recommending, in 1930, the administration of distilled water intravenously to swell the contracted brain in such cases.

In 1941, I reported a technic which has been regularly used since, when at the operating table the brain fails to expand to occupy the space previously occupied by the hematoma. The subdural space is filled with distilled water and a small soft rubber drainage tube is led out of the subdural space. The wound is then closed in layers tightly about the tube. A clamp is placed on the tube, the head is dressed and the patient is returned to bed. He is given 1,000 cc. of distilled water intravenously and another 1,000 cc. of isotonic solution of sodium chloride. The clamp is removed from the tube four to six hours later, and the tube is removed twenty-four hours later.

The danger of hemolysis after the intravenous administration of distilled water is obvious. The patients all exhibit mild hemoglobinuria for a day or two after the injection, but other ill effects have not been observed clinically. The use of this procedure is justified by a comparison of the previous poor result constantly encountered in this type of case with the successful result of this technic. It has now been used in 16 patients. All recovered with 1 exception; in this patient the technic was modified by the omission of the intravenous administration of distilled water; only isotonic solution of sodium chloride was given intravenously. This patient followed the usual course of such cases in past experience; he failed to rally, remained in coma and died forty-eight hours later. It is felt that this technic has now been used sufficiently often to demonstrate its value.

TABLE 4.—*Classification of Lesions and of Mortality of Patients*

	Hematomas		Cerebral Injury	
	Unilateral	Bilateral	Associated	None
Total	86	14	29	71
Recovered	80	10	10	60
Dead	26 (31%)	4 (29%)	19 (66%)	11 (15%)

A careful study of the results with different sizes of clot was made. Twenty-four clots were classified as small, 3 to 10 mm. thick (clots less than 3 mm. thick were not included in this series) and not over an estimated 30 cc. in volume. Forty-nine hematomas were considered moderate in size, 1 to 2 cm. thick or 30 to 60 cc. in volume. Twenty-seven patients had large hematomas, 2 cm. or more thick. There was no essential difference in the mortality in these groups. It is apparent, as previously stated, that the age of the patient and the stage of the clot (tables 1 and 2) are of importance in determining mortality. Table 4 shows that whether the clot is unilateral or bilateral is likewise unimportant, but that the factor of associated injury to the brain is most important of all. Associated injury to the brain here means gross cerebral contusion or laceration noted at operation or necropsy. Since exploration was limited in most cases to openings 1 to 3 cm. in diameter over each parietal region, it is likely that many surviving patients had injury to the brain that was not revealed at operation. Since associated injury to the brain is generally seen in acute cases, the reason for the high mortality in that group is

26. Cohen, J.: Chronic Subdural Accumulations of Cerebrospinal Fluid After Cranial Trauma, Arch. Neurol. & Psychiat. **18**: 709-723 (Nov.) 1927.

obvious. It can be seen from tables 2 and 4 that the mortality for patients operated on a week or longer after the injury was only 14 per cent and that for patients without associated cerebral injury was only 15 per cent. The correlation is obvious.

SUMMARY

Subdural hematoma is, as a rule, primarily caused by injury to the head. Occasionally, such predisposing causes as tumor or a vascular anomaly are seen. The initial hemorrhage is subdural rather than intradural.

If the immediate hemorrhage is massive, there is usually a severe associated injury to the brain and corresponding severity of symptoms. The mortality is high in this group, and surgery is only rarely of value. If the patient survives the injury to the brain these hemorrhages are generally absorbed because of their communication with the subarachnoid space through tears in the arachnoid.

Moderate or small primary subdural hemorrhage gradually grows by osmosis of cerebrospinal fluid through the arachnoid. The hematomas gradually develop neomembranes, first on the dural side.

Diagnosis is based on a history of trauma (if available) and on the progressive nature (often with fluctuation) of the symptoms. Examination of the spinal fluid is extremely important. In the last analysis the diagnosis is established by exploratory bur holes.

Exploration should always be bilateral. Drainage is usually possible through a single bur hole; occasionally multiple bur holes or an osteoplastic flap is necessary. If during surgical intervention the brain does not expand to fill the space previously occupied by the clot, special measures such as the satisfactory procedure described herein to induce such expansion should be instituted.

ABSTRACT OF DISCUSSION

Dr. A. W. Adson, Rochester, Minn.: I should like to comment on some of the sequelae that develop in connection with subdural hematoma. Dr. Voris has explained that there are a number of patients who come with symptoms of increased intracranial pressure, with or without definite neurologic observations. The patient may show evidence of papilledema, and naturally one suspects the presence of a brain tumor. It is true that after one uncovers the finding at operation one will elicit some story that reveals a mild accident or head injury. I recall a young man who was blowing a large tuba horn and subsequently developed headache. He came to me several months later. Exploration for brain tumors have been done on a number of these patients. A subdural hematoma of some duration has a membrane both on the dural side and on the arachnoid side. As one palpates this membrane one becomes aware of the fact that one is dealing with a fluid mass. Some patients have a refilling of this cavity when an attempt has been made to wash out the blood clot by irrigation. I think that is due to the fact that the blood has not all become liquefied, and there remains a fairly good sized clot along the edge. Because this remains, more osmosis takes place and the recurrence might follow. Therefore it is rather important to make sure that this cavity has been thoroughly irrigated and that all the blood clots have been removed. If one has occasion to turn a bone flap it is wise to attempt to remove the membrane, because in so doing one undoubtedly relieves the restraining effect which sometimes prevents the refilling of the brain itself. I had a patient who apparently recovered from the washing out and draining of the subdural blood and returned later with a brain abscess and also an abscess in this cavity between the arachnoid and the dura. In the treatment of these cases my associates and I have used a solution of penicillin. We have attempted to drain the abscess and then fill the cavity. If, however, a brain abscess has developed in connection with the old subdural clot, one of course treats it in the usual manner. It is not uncommon, if there is occasion to open up one of these with a bone flap, to find a white, raised mass, due undoubtedly to the collection of fibrin white cells and other structures in the blood, so that again I want to emphasize that it is extremely important to clean out all the old blood or any white clot that may be present. If one has occasion to open the skull, the membrane as well as the old blood should be removed.

THE MANAGEMENT OF BACTERIAL INFECTIONS OF THE SKIN

DONALD M. PILLSBURY, M.D.
Philadelphia

Bacteria play roles of varying importance in a wide variety of diseases of the skin in man. The problem of the management of bacterial infections of the skin cannot be dismissed simply by a discussion of the diseases produced, the bacteria concerned and the advantages and disadvantages of the various antibacterial agents now available, especially since the latter still have certain definite shortcomings. The management of the more difficult and more resistant cutaneous infections can be improved by a better understanding of the manner in which the skin resists and harbors bacteria and of some of the mechanisms by which bacteria produce harmful effects.

The experience of the Army Medical Corps during recent years has furnished much information in regard to the potentialities of cutaneous diseases in the production of disability in young male adults. The amount of disability from this source was surprisingly large, and various types of pyoderma were responsible for much of it. The overall experience of the Army in this regard has recently been summarized by Pillsbury and Livingood.[1] During the year 1944, the number of hospital admissions because of diseases of the skin varied between 3,731 and 10,399 for each 100,000 troop strength in different theaters of operation. These figures do not include admissions to the sick list in field medical stations or dispensaries, in which the number of dermatologic patients varied between 15 and 60 per cent of the total.

In troops in the United States, the average number of hospital admissions by reason of a cutaneous disease was 42 per thousand troop strength per year, while in overseas stations the average number was almost twice as great, or 80 per thousand troop strength per year. Patients who were returned from an overseas station because of a cutaneous disease had a total hospital stay averaging 5.5 months, as long as that for many major battle casualties or serious medical diseases. In the Southwest Pacific area, between November 1944 and November 1945 approximately 15 per cent of all patients evacuated to the United States were sent home because of a cutaneous disease. In some months this was the most common reason for evacuation, with

The studies from the Department of Dermatology cited in this paper were aided by a grant from the Smith, Kline & French Laboratories.

Read in the General Scientific Meetings at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 1, *1946*.

Because of lack of space, this article is abbreviated in The Journal by omission of portions of the text and footnotes. The complete article will appear in the author's reprints.

[1] Pillsbury, D. M., and Livingood, C. S.: Experiences in Military Dermatology: Their Interpretation in Plans for Improved General Medical Care, Arch. Dermat. & Syph., to be published.

the exception of neuropsychiatric disorders; and in all months it was a more frequent cause of evacuation from that area than battle casualties.

Pillsbury and Livingood state that some form of pyoderma was regularly among the first five sources of disability from cutaneous disease, and that "cutaneous pyogenic infections are a far more important cause of chronic disabling eruptions than are superficial fungous infections."

Certain striking advances in the treatment of cutaneous infection have been made during recent years, but unfortunately a nonsensitizing and completely satisfactory method of treatment is not yet available. In particular, local penicillin therapy is producing contact dermatitis in an increasing percentage of patients, and further study of the mechanism of this reaction and of means to prevent it is needed.

CLASSIFICATION OF CUTANEOUS INFECTIONS

In the selection of the proper type of treatment, division of cutaneous infections into certain broad classifications is useful. Some infections are acute and primary, arising rapidly in skin which was previously normal. Other infections are acute and secondary, arising in skin which has had its integrity disturbed by some previous disease or injury. Other infections are chronic and recurrent, at times presenting great difficulties in cure. The following practical classification has proved useful.[2] In it, certain complex descriptive dermatologic terms have been omitted because they are more confusing than informative.

Primary Acute Superficial Infections.—Primary acute superficial infections include impetigo of various types, acute infectious eczematoid dermatitis and superficial acute ecthyma. Hemolytic Staphylococcus aureus and/or streptococci (ordinarily Lancefield group A) are concerned in the causation of such eruptions. The character of the lesions varies considerably, depending on the virulence of the bacteria concerned, the defensive reaction of the skin to infection and the site of involvement, whether on smooth skin, about hairs or in intertriginous areas. Factors such as perspiration (for instance, in tropical impetigo), functional or organic disturbances of the circulation and seborrheic "diathesis" greatly influence the character and course of the infection.

Acute Superficial Infections Occurring as a Complication of Some Preexistent Dermatosis.—Bacterial infection may appear as a complication of a wide variety of dermatoses, but in the following diseases it is most frequently observed: dermatitis and eczema, superficial fungous infections, seborrheic dermatitis, parasitic diseases and neurodermatitis. Bacteria rapidly gain a foothold in skin which is already diseased, and the problem of their removal is complicated by the fact that such skin reacts more frequently to treatment than does skin which was previously normal. Concomitant treatment of an underlying dermatosis, for instance, scabies or seborrheic dermatitis, may be necessary before the bacterial infection can be controlled completely. It is of the greatest importance that secondary bacterial infection of any eruption be recognized and controlled as promptly as possible, if chronicity of the infection is to be prevented.

Chronic Eczematous Lesions in Which Pyogenic Infection is Playing a Variable but Significant Role.—The chronic eczematous lesions in which pyogenic infection is playing a variable but significant role have certain characteristics in common, but may vary considerably in appearance and localization. The features in common are (1) eczematous appearance, often with little evidence that bacterial infection is present; (2) sharp circumscription of each particular individual lesion, usually; (3) chronicity; (4) occasional acute pyogenic flare-ups, of variable intensity; (5) a definite tendency of the patient to be hypersensitive to various bacterial derivatives, particularly staphylococcus toxoid, and (6) liability to explosive dissemination of the process to other parts of the cutaneous surface, sometimes with an accompanying systemic reaction. Lesions of this group of eczematous dermatoses are most frequently observed on the lower legs, the forearms and the hands. They are variously diagnosed, with reason, as nummular eczema (an unsatisfactory descriptive term), seborrheic dermatitis, chronic eczematoid dermatitis, chronic contact or food dermatitis and neurodermatitis.

Chronic Deep Ulcers.—While bacterial infection is often chiefly responsible for chronic deep ulcers, thorough general medical study of the patient is absolutely essential to the intelligent management of any chronic ulcer. In addition, the bacteriologic study of the lesion should be especially thorough, with culture by both aerobic and anaerobic methods. Such patients should never be treated with penicillin by injection until the result of the serologic test for syphilis is known, or, at least, blood has been taken for it.

Acute and Chronic Infections of the Skin Appendages.—Acute and chronic infections of the pilosebaceous apparatus and the sweat glands (folliculitis, furunculosis, carbunculosis, hidradenitis) are often extremely difficult to cure, and a combination of medical, surgical and radiotherapeutic methods may be necessary. Relapses are commonly seen, and thorough study to determine what factors other than infection are operative is often necessary.

Other infections of the skin and subcutaneous tissue include cellulitis, both acute and recurrent, erysipelas, erysipeloid of Rosenbach, venereal diseases and cutaneous diphtheria. Discussion of the management of these infections will not be attempted in this paper.

BACTERIOLOGIC AND THEORETIC CONSIDERATIONS

Certain established facts and hypotheses in regard to the bacterial flora of the normal and diseased skin are of considerable practical value in the management of acute and chronic cutaneous infections. The important general principles are:

1. *The Number of Bacteria on Normal Skin.*—The human skin is the habitat of an enormous number of bacteria, which vary to a considerable degree in kind and number in different persons, in various parts of the body and under different conditions of environment, hygiene, apparel, perspiration and contaminating bacterial contact.

A method for determining the number of bacteria on the hands and forearms has been devised by Price,[3] which has proved useful in determining the effects of mechanical "degerming" of the skin and of various antiseptics. This method has been employed, with some modifications, in several studies by other workers (Pohle,[4] Pillsbury,[5] Cromwell,[6] Shaffer[7] and their associates).

---

[2] Pillsbury, D. M.: Sulfonamides in Dermatology, Brit. J. Dermat. 56: 68, 1944.

[3] Price, P. B.: The Bacteriology of the Normal Skin: A New Quantitative Test Applied to a Study of the Bacterial Flora and the Disinfectant Action of Mechanical Cleansing, J. Infect. Dis. 63: 301, 1938.

The number of bacteria removable from the hands and forearms of normal persons by a standard series of scrubs of a total duration of fifteen minutes has varied between 4 million and 40 million in my experiments.[5] The number of bacteria shows great variation from person to person and is influenced greatly by hygiene, particularly of the nails, by the wearing of rubber[3] or other gloves which produce increased warmth and perspiration, by contact with infected patients and by covering the skin with a relatively impermeable film, such as calcium soap.[8]

2. *Types of Bacteria on Normal Skin.*—The types of bacteria recovered from normal skin show considerable variation. The concept of Price that cutaneous bacteria may be divided into a transient and resident flora is of great practical value, although the division is sometimes not clear-cut. The transient bacteria are easily removed from the skin by a variety of means, but the resident bacteria are difficult to kill or remove. In particular, it has been demonstrated that pathogenic bacteria and fungi may suddenly become part of the resident flora and may persist for a long time.

Beta hemolytic streptococci, particularly those of the Lancefield[11] group A, are infrequently isolable from the normal human skin unless the subject is suffering from an infection elsewhere. Staphylococci are, however, frequently recovered, though coagulase-positive hemolytic Staph. aureus is found with far greater frequency on the frankly infected or eczematous skin than on normal skin.

3. *Cutaneous Self-Disinfection.*—The normal skin has an enormous power for self disinfection, the mechanism of which is not yet clearly understood. Burtenshaw[13] has recently reviewed this subject. He concluded that while such factors as desquamation, desiccation, acidity and sunlight contribute to the self-sterilizing powers of the skin, they do not adequately explain its capacity in this regard. In his opinion, it is probable that the whole range of fatty acids of the acetic series, from formic to stearic and oleic, and a few other organic acids are important agents in killing bacteria, fungi and viruses on the surface of the skin.

4. *The Factor X in Cutaneous Infection.*—It has been established by experiments on the human skin that it is often difficult to produce infection by the introduction of bacteria or infectious material derived from a patient suffering from a cutaneous infection.[14] This difficulty has been well demonstrated in impetigo, which is presumed to be almost entirely due to the action of bacteria and to be highly contagious. The most recent experimental studies in this regard have been carried out by Bigger and Hodgson[15] and by Sheehan and Fergusson.[16] The former attempted to produce impetigo of the skin of volunteer subjects and of the unaffected skin of patients with impetigo by various means, without success. Sheehan and Fergusson were slightly more successful in producing impetigo experimentally.

It is difficult to escape the conclusion that, as Bigger and Hodgson have pointed out, there is a factor X in the development of impetigo. The disease varies in contagiousness from the persistent epidemics which were formerly encountered in nurseries for the newborn to the relative infrequency with which impetigo is encountered among adults, such as physicians and nurses, who are repeatedly exposed to the disease.

5. *Superficial Bacterial Infection as a Sensitizing Agent.*—The potentialities of superficial bacterial infection as a sensitizer of the skin are manifold. The bacteria of the skin in patients with chronic eczema are almost always a significant component in the variable etiologic backgrounds of such conditions. Stokes[18] has long been interested in this problem and has written a number of papers dealing with different aspects of the "infection-allergic complex." He and others have demonstrated that in the course of almost any chronic eczematous disease, ingestant, inhalant, contactant, infective, general medical and psychosomatic influences are frequently interwoven and variously predominant. With the employment of this useful concept, it is at once apparent why any one of these various methods of approach to the problem of chronic eczematous eruptions is useful and often successful, at least temporarily.

It is of interest to examine some of the evidence concerning the mechanisms by which bacteria may contribute to exacerbation or persistence of eczematous disease. As has been stated previously, skin that is chronically inflamed almost inevitably receives some new strains of bacteria into residence. At times these may quickly produce acute, severe infections. Examples of this include the explosive impetigos and infectious eczematoid dermatitis occasionally seen in patients with atopic dermatitis. Another example is the persistent furunculosis which sometimes follows dermatitis or scabies. The furunculosis often persists long after the original dermatosis has disappeared.

On the other hand, bacteria which become resident in inflamed skin frequently do not produce overt evidences of infection but may impede the progress of the skin to normality by acting as potent skin sensitizers. One strong clinical evidence of this is the frequency with which patients react to injections of staphylococcus toxoid or of a preparation of staphylococcus toxoid and bacterial antigen. Evidence of this

sensitivity may be seen in a decided local reaction at the site of intradermal injection of a small amount of toxoid, or by an exacerbation of the dermatitis after such an injection or even by the precipitation of a generalized id reaction. The latter reaction may sometimes be accompanied by evidence of systemic reaction. Similar reactions may be elicited at times by the injection of simple vaccines of staphylococci or streptococci isolated from the skin of the patient, though not as frequently as with a stock staphylococcus toxoid, in my experience.

While one must be cautious in interpreting such sensitivity as having been directly induced by the growth of bacteria in an area of damaged skin, there is some experimental evidence that this is actually the case. Hecht and others [19] have shown that under certain conditions, persons may become sensitized to the slightly denatured substances of their own organs, and that organ-specific antibodies may then be produced. The antibody may, in turn, damage the particular organ in vivo and in situ and may thus produce clinical disease. These investigators injected sections of rabbit skin intramuscularly at one site and staphylococcus toxin intradermally at other sites. The injected rabbits developed percipitins against soluble rabbit skin antigen. However, in animals injected with skin alone or toxin alone and in untreated controls anti-skin precipitins were not observed.

THE CLINICAL MANAGEMENT OF PYODERMAS

One principal aim in the treatment of any bacterial infection is, obviously, to eliminate the offending bacteria as rapidly as possible. It is equally obvious, however, that the treatment must be of an order which will not produce a reaction which may be more severe or persistent than the original disease. In the treatment of acute superficial infections such as impetigo, ecthyma and infectious eczematoid dermatitis, it is usually possible to cure the disease within a period of a week. Until recently it was believed that topical penicillin therapy was the initial treatment of choice, but the disturbing appearance of an increasing incidence of sensitivity reactions in patients so treated is producing a considerable change in this view. It is probable that further experience will indicate that topical penicillin therapy is much less safe, and therefore less useful, than was previously believed.

In the following paragraphs, the various types of treatment of bacterial infections of the skin in common use at the present time will be outlined, together with comments on their usefulness. Evaluation of certain older methods of treatment is difficult, because adequate data, including follow-up results, have never been collected in regard to many of them, to my knowledge.

Topical Penicillin Therapy.—A large number of reports on the topical penicillin method of treatment have appeared since it came into general use in the armed forces in 1944. Two particularly outstanding studies have been made, one by Davies and his associates [23] under the auspices of the Royal Army Medical Corps and the other by Hopkins and Lawrence [24] at the instance of the Surgeon General, United States Army. Davies treated 182 patients affected with various types of superficial pyoderma with penicillin applied topically. Careful bacteriologic studies were performed throughout the study with, of particular interest, grouping of the streptococci recovered according to the Lancefield classification. The distribution of patients treated was as follows: annular impetigo (staphylococcic) 17, impetigo (streptococcic) 12, ecthyma 15, furunculosis 6, impetiginous seborrheic dermatitis 132.[25]

The penicillin in this study was ordinarily applied by means of an aqueous solution containing 1,000 units per cubic centimeter which was sprayed on the skin at intervals of four hours. In both staphylococcic and streptococcic impetigo, penicillin spray produced more rapid healing than a control treatment, by an average of 4.6 days. It was concluded that it was a superior method of treatment in such cases. The results in ecthyma were not considered superior to other methods of treatment. In impetiginous seborrheic dermatitis, penicillin spray was occasionally, but not always, more effective than other methods.

It is noteworthy that the Davies workers were usually able to recover the original bacteria from the lesions after penicillin therapy, and this has been confirmed by the study of Hopkins and Lawrence. Davies and his associates encountered no instances of reactions attributable to a sensitivity to penicillin in their cases. This is at variance with recent other studies, and with my own experience in studies made with Templeton,[26] Wrong,[27] Gottschalk [28] and other associates.

Hopkins and Lawrence [24] treated a series of 618 soldiers suffering from various types of pyogenic infections by local applications of penicillin incorporated in three types of bases, in strengths varying from 100 to 10,000 units per gram. The bases used were an oil-in-water emulsion (U. S. Army supply item no. 1173800), a bentonite gel, and a glycol-carbowax mixture. Apparently these bases were equally satisfactory. A strength of 100 units per gram was inferior to a strength of 500 units per gram. Occasionally, higher concentrations of penicillin were necessary, but these concentrations produced an increased incidence of sensitization to penicillin.

Hopkins and Lawrence concluded that topical penicillin therapy is rapidly effective in the majority of cases of impetigo, ecthyma and the pyogenic complications of dermatophytosis. In the latter condition, the incidence of control of the infection was higher, and the time required to attain it less, than in lesions which were treated with 5 per cent sulfathiazole, 10 per cent tannic acid, 20 per cent zinc peroxide or 0.5 per cent benzolkonium chloride solution. It is noteworthy also, in passing, that rest and protection of the inflamed skin by a simple dressing were as effective as penicillin therapy in a small series of cases of mildly infected dermatophytosis of the feet.

[25] The concept of seborrheic dermatitis as employed in this and many other papers appearing in the British medical literature is considerably more elastic than the usual American concept of this disease. Many of the cases reported would be regarded by American observers as instances of superficially infected intertrigo, patchy eczematoid dermatitis, neurodermatitis or nummular eczema.

[28] Gottschalk, H. R., and Weiss, R. S.: Epidermal Sensitivity to Penicillin, Arch. Dermat. & Syph. **53**: 365 (April) 1946.

The results of topical penicillin therapy in folliculitis of the beard were not striking; the infections of only one third of the patients were cleared up, even temporarily. In secondarily infected eczematous dermatitis, the bacterial infection was controlled in 40 per cent of the cases, but sensitization to penicillin was encountered in 25 per cent of the cases. Hopkins and Lawrence observed that penicillin was seldom effective against seborrheic dermatitis, intertrigo, folliculitis of the trunk extremities, or acne.

Sensitivity to Penicillin Applied Locally.—Hopkins and Lawrence found an overall percentage of sensitivity of 11 per cent; the highest number of reactions occurred in eczematoid dermatitis and the lowest in impetigo, ecthyma and secondarily infected dermatophytosis. Wrong [27] states that "my impression is that the incidence of dermatitis is increasing by leaps and bounds and is well over 10 per cent at present." Gottschalk and Weiss [28] found that 24 of 200 persons who apparently had had no previous contact with penicillin gave a positive reaction to the initial patch test. In addition, by means of a patch test they were able to sensitize 4.5 per cent of 200 persons to penicillin ointment.

Templeton, Lunsford and Allington [26] have cited a long list of published reports of local reactions to penicillin, which have occurred in physicians and chemists handling the drug, after the application of a wet dressing of penicillin and after the use of penicillin lozenges and troches and penicillin eye drops. I have observed instances of all these reactions, particularly of the sensitivity which develops in physicians, nurses and corpsmen who are frequently exposed to penicillin.

Fortunately, the local reactions to penicillin are usually mild and subside promptly. In addition, it is possible for some patients to continue the use of penicillin locally with disappearance of the sensitivity, a process which has a well known corollary in the "hardening" of the skin which occurs in workers exposed continuously to occupational contactants. On the other hand, the swelling, redness and vesiculation may at times be decided and may require prompt discontinuance of the penicillin therapy. Two extremely important considerations, both of which have had a disappointing corollary in the case of local sulfonamide therapy are, first, it is probable that as more persons are repeatedly exposed to contact with penicillin by application or injection, the incidence of severe reactions will increase; second, it is probable that sensitivity of the epiderm induced by local application will be succeeded in some patients by induced sensitivity of the dermal and vascular structures, with the result that reactions will follow the subsequent parenteral administration of penicillin.

Sulfonamide Therapy in Superficial Pyoderma.—Local sulfonamide therapy of superficial infections of the skin is rarely justifiable; some observers believe that it has no place whatever in modern therapy. In the clinic with which I am associated, the initial results with local sulfathiazole therapy were excellent, and almost no untoward reactions of any severity were seen in the first 200 patients treated.[29] Many observers, including myself,[30] then began to perceive reactions of severity and chronicity if the sulfonamide preparation had been used for prolonged periods, particularly in cases of eczematous pyoderma. During the war, 5 per cent sulfadiazine in an emulsion base was extensively used on soldiers for various superficial infections. If used properly for acute primary infections for periods not longer than five days it did relatively little harm, but it was all too frequently applied for prolonged periods without medical control and with disabling results for the patient. It is impossible to restrict the use of an easily available ointment preparation sufficiently to prevent its misuse by the patient or by others.

Local Hygiene.—The cleaning up and gentle débridement of superficial cutaneous infections is an absolute *sine qua non* to the maximum effectiveness of any method of treatment. It is as important to open a pustule or remove epithelial debris gently as it is to drain a deep abscess, in terms of prompt cure of the infection. Various solutions are fairly effective in promoting this cleaning up process, not through any particular antibacterial power, but because they soften debris and allow the immune response of the skin and the action of other treatment to proceed effectively. Isotonic solution of sodium chloride, boric acid solution and 0.01 per cent potassium permanganate solution are all useful. In recent laboratory experiments, none of these substances had any rapid adverse effect on penicillin solution in the strengths ordinarily employed.

Rest and exposure of the affected part to air are also important features of treatment. It is difficult to cure a secondary infection of the foot, however mild, when the patient encases his foot in a shoe and subjects the foot to trauma for twelve to eighteen hours a day.

Penicillin by Injection.—In recent months, it has been my practice to employ penicillin by injection in superficial pyodermas, whenever this procedure is possible. If the infection is acute and caused by penicillin-sensitive bacteria, such therapy is almost always rapidly curative. This treatment has serious disadvantages by reason of the expense involved, but this is not a medical reason. If penicillin in water or isotonic solution of sodium chloride is employed, treatment is inconvenient, but treatment may be carried out in the office with penicillin in peanut oil and beeswax solution. Two or three daily injections of 150 thousand to 300 thousand units each are ordinarily sufficient. Whether or not the incidence of severe reactions to penicillin administered parenterally will prove a significant drawback to such treatment remains to be seen, but at present it is my experience that the parenteral injection of penicillin is equal or superior to topical penicillin therapy in the treatment of superficial cutaneous infections and is productive of fewer reactions.

Various Other Methods of Treatment.—Ammoniated Mercury: The use of an ointment which contains ammoniated mercury in a strength above 5 per cent is rarely necessary. In many patients, particularly if there is much oozing from the lesions or if the skin is oily, a suspension of ammoniated mercury in a "shake" lotion, such as calamine, is superior to the ointment.

[30] Livingood, C. S., and Pillsbury, D. M.: Sulfathiazole in Eczematous Pyoderma: Sensitization Reaction to Successive Local and Oral Therapy, J. A. M. A. **121:** 406 (Feb. 6) 1943.

Gentian Violet Medicinal: Gentian violet medicinal is widely used, but it is messy and disfiguring.

Acriflavine: Acriflavine is expensive and messy but often extremely effective. It is best applied in compresses of 0.01 per cent strength. Its use in conjunction with sulfonamides may produce an increased tendency to sensitivity to sunlight.[32]

Castellani's Carbol Fuchsin Paint: Castellani's carbol fuchsin paint is often the single most effective local application in chronic low grade eczematous infections of the skin. It is disfiguring in color but not as messy as gentian violet medicinal. It is decidedly antipruritic, and local irritation from it is not encountered as frequently as might be expected from the strength of phenol and resorcinol in the compound.

Silver Nitrate: Silver nitrate may be used in compresses of 0.1 per cent strength or painted on in 1 per cent aqueous solution. It is an extremely useful drug in superficial infections and almost reactionless, unless excessive strengths are used. It is important to apply the solution as directly as possible to the site of infection, not merely on top of crusts and epithelial debris.

Quinolor Compound Ointment: Quinolor Compound Ointment[33] is particularly useful in chronic follicular infections, though often effective in other pyodermas. It occasionally produces some burning when applied, though severe local reactions to it are uncommon.

Benzalkonium Chloride Solution (0.5 per cent): Benzalkonium chloride solution (0.5 per cent) is a soothing, apparently reactionless, compound which has had extensive use by Hopkins and Lawrence. Ordinarily, however, it is not sufficiently antibacterial alone for effective use against acute infections.

Other preparations are recommended, but those already mentioned have been the most useful in my experience. It cannot be emphasized too strongly that the use of chemical irritants or of highly sensitizing compounds on infected, inflamed skin will result in severe reactions, and in many instances may lead to prolongation of partial disability over a period of weeks or months. Instances of this are regularly seen. In particular, tincture of iodine should never be used; it is a cauterant and skin-sensitizer, and too frequently adds to the burden under which the diseased skin is already laboring.

SUGGESTED TREATMENT REGIMENS[34]

Suggested Treatment Against Impetigo, Ecthyma, Acute Infectious Eczematoid Dermatitis, and Acute Pustular Folliculitis.—1. Thorough gentle cleaning of the involved site by means of soap and water, compresses of isotonic solution of sodium chloride or 0.1 per cent potassium permanganate solution for twenty minutes two to six times a day, gentle mechanical opening of all pustules and careful removal of softened cutaneous debris are of importance.

2. Penicillin therapy is recommended. It is my opinion that penicillin by injection, especially in vehicles designed to slow the absorption and maintain an adequate serum concentration of the drug for twelve to twenty-four hours, is probably preferable to local penicillin therapy. The dose for adults should be of the order employed for any acute bacterial infection. If the penicillin oil and beeswax mixture is used, a single injection of 1 cc. which contains 300,000 units of penicillin once a day is ordinarily adequate. However, in simple impetigo, for instance, local penicillin therapy is much simpler and less expensive. The total period of application should not be longer than five days, even at the risk of relapse. No more ointment than can be used efficiently during this time should be prescribed. A concentration of 500 units per cubic centimeter or gram is best, though in all-grease vehicles, a higher concentration may be necessary to allow sufficient diffusion of penicillin to the site of infection. The penicillin may be applied four or five times a day in an aqueous spray or compress, in various types of emulsion bases (including "brushless shaves") and in all-grease bases. Theoretically a solution or emulsion base should be most effective, though clinical studies do not confirm this entirely. Emulsion bases allow reduction in the penicillin content on standing, but are sufficiently potent for at least a week at room temperature. All-grease bases show no significant deterioration on standing. An adequate dressing should be used on ecthyma lesions.

3. If local penicillin therapy is not observed to produce improvement within seventy-two hours, a change to something else is advisable. Ammoniated mercury, silver nitrate, alibour water and Quinolor ointment, in that respective order, are the best alternatives, in my experience.

Suggested Treatment of Acute Secondarily Infected Dermatitis, Eczema, Dermatophytosis, and Similar Lesions.—1. Penicillin should not be applied locally, except possibly in secondarily infected dermatophytosis; parenteral injection of penicillin is the treatment of choice. The most commonly encountered reaction will be an inflammatory reaction at the site of the active or quiescent fungous infection, or a dermatophytid-like reaction.

2. Bacterial cultures and determination of the sensitivity to penicillin of the bacteria recovered should be performed whenever possible.

3. Sulfonamides should not be applied locally.

4. Undue activity and trauma of the affected part by shoes or clothing should be avoided so far as possible.

5. Nonirritating mildly antiseptic soaks or compresses are useful. These may be used frequently, but the diseased skin should have adequate exposure to the air several times a day. Gentle mechanical débridement of the affected site, taking care not to injure underlying or surrounding skin, is important.

6. If penicillin is not promptly effective (within seventy-two hours), a change to a sulfonamide compound (sulfadiazine and/or sulfamerazine) administered by mouth should be considered, along with a change

---

[32] Peterkin, G. A. G.: Sulfonamide Rashes: An Analysis of Five Hundred Cases Seen in North Africa and Italy, Brit. M. J. 2:1 (July 7) 1945.

[33] Quinolor Compound Ointment, E. R. Squibb & Sons, contains 10 per cent benzoyl peroxide and 0.5 per cent Quinolor (a mixture of 3 chlorine derivatives of 8 hydroxyquinoline) in a base of equal parts of petrolatum and wool fat.

[34] Since this paper was written, MacKee and others (MacKee, G. M., Sulzberger, M. B., Herrmann, F., and Karp, F. L.: The Treatment of Pyodermas with an Interface Active Solution of Tyrothricin. J. Invest. Dermat. 7:4 [Aug.] 1946) have reported favorable clinical response in 232 patients with various cutaneous diseases caused or complicated by pyogenic infections. Most of the diseases treated were those involving the hair follicles, and it may be presumed that staphylococci were the chief causative organisms. The solution used contained 0.1 per cent tyrothricin in a vehicle which had previously been shown to enhance the penetration of other substances into the skin. The results reported by these writers are excellent, and the preparation used was found to be nonirritating and nonsensitizing.

The results of topical penicillin therapy in folliculitis of the beard were not striking; the infections of only one third of the patients were cleared up, even temporarily. In secondarily infected eczematous dermatitis, the bacterial infection was controlled in 40 per cent of the cases, but sensitization to penicillin was encountered in 25 per cent of the cases. Hopkins and Lawrence observed that penicillin was seldom effective against seborrheic dermatitis, intertrigo, folliculitis of the trunk extremities, or acne.

Sensitivity to Penicillin Applied Locally.—Hopkins and Lawrence found an overall percentage of sensitivity of 11 per cent; the highest number of reactions occurred in eczematoid dermatitis and the lowest in impetigo, ecthyma and secondarily infected dermatophytosis. Wrong[27] states that "my impression is that the incidence of dermatitis is increasing by leaps and bounds and is well over 10 per cent at present." Gottschalk and Weiss[28] found that 24 of 200 persons who apparently had had no previous contact with penicillin gave a positive reaction to the initial patch test. In addition, by means of a patch test they were able to sensitize 4.5 per cent of 200 persons to penicillin ointment.

Templeton, Lunsford and Allington[26] have cited a long list of published reports of local reactions to penicillin, which have occurred in physicians and chemists handling the drug, after the application of a wet dressing of penicillin and after the use of penicillin lozenges and troches and penicillin eye drops. I have observed instances of all these reactions, particularly of the sensitivity which develops in physicians, nurses and corpsmen who are frequently exposed to penicillin.

4. Undue activity and trauma of the affected part by shoes or clothing should be avoided so far as possible.

5. Nonirritating mildly antiseptic soaks or compresses are useful. These may be used frequently, but the diseased skin should have adequate exposure to the air several times a day. Gentle mechanical débridement of the affected site, taking care not to injure underlying or surrounding skin, is important.

6. If penicillin is not promptly effective (within seventy-two hours), a change to a sulfonamide compound (sulfadiazine and/or sulfamerazine) administered by mouth should be considered, along with a change

---

[32] Peterkin, G. A. G: Sulfonamide Rashes: An Analysis of Five Hundred Cases Seen in North Africa and Italy, Brit. M. J. 2:1 (July 7) 1945.

[33] Quinolor Compound Ointment, E. R. Squibb & Sons, contains 10 per cent benzoyl peroxide and 0.5 per cent Quinolor (a mixture of 3 chlorine derivatives of 8 hydroxyquinoline) in a base of equal parts of petrolatum and wool fat.

[34] Since this paper was written, MacKee and others (MacKee, G. M., Sulzberger, M. B., Herrmann, F., and Karp, F. L.: The Treatment of Pyodermas with an Interface Active Solution of Tyrothricin. J. Invest. Dermat 7:4 [Aug] 1946) have reported favorable clinical response in 232 patients with various cutaneous diseases caused or complicated by pyogenic infections. Most of the diseases treated were those involving the hair follicles, and it may be presumed that staphylococci were the chief causative organisms. The solution used contained 0.1 per cent tyrothricin in a vehicle which had previously been shown to enhance the penetration of other substances into the skin. The results reported by these writers are excellent, and the preparation used was found to be nonirritating and nonsensitizing.

to some other method of local nonirritating antiseptic therapy.

7. If there is an underlying dermatophytic infection, the use of a preparation containing undecylenic acid is recommended. Irritating fungicides are harmful.

Suggested Treatment for Chronic Infections, Including Those of the Eczematous Type.—1. Penicillin should not be used locally, except possibly in noneczematous chronic follicular infections and ulcers. Parenteral injection is much the preferable method of administration.

2. Sulfonamides should never be applied locally.

3. Bacterial culture, together with determination of the sensitivity to penicillin of the bacteria recovered, is extremely useful.

4. The patient should be studied completely, and a careful history should be taken to determine the factors in regard to contactants, ingestants, trauma and general medical consideration involved.

5. Initial local treatment with bland preparations as for a dermatitis is almost always best.

6. In some instances, the administration of sulfonamides, with small initial doses, is effective.

7. Such preparations as Castellani's carbol fuchsin paint, 2 per cent silver nitrate or, if there is an underlying seborrheic dermatitis, a sulfur-salicylic acid-tar preparation are variously useful.

8. Roentgen ray therapy is sometimes helpful, but one is impressed with its gross misuse in the treatment of many dermatologic patients. It should be infrequently necessary and carefully administered, and it should not be used as a substitute for careful study of the several possible etiologic backgrounds.

SUMMARY

1. Bacteria are responsible, in greater or less degree, for a considerable proportion of the disease affecting the human skin. The disability produced by bacteria is greater than the disability produced by fungous infections. Hemolytic Staphylococcus aureus and beta hemolytic streptococci, alone or in combination, are the chief offenders.

2. The changes which are produced by bacteria in the skin may be acute and fulminating or extremely chronic. Bacteria, acting through their toxic or allergenic effects, are responsible for chronicity in many cutaneous lesions which do not appear primarily infectious.

3. The normal human skin harbors an enormous number of bacteria which are ordinarily harmless. These may be divided roughly into a resident and a transient population (Price). The resident population usually remains fairly stable, both quantitatively and qualitatively, in any person. However, some influences, particularly heat and moisture, cause considerable changes in the number of bacteria on the normal skin. Pathogenic bacteria may sometimes suddenly become members of the resident flora of the skin and may then be extremely persistent and difficult to dislodge.

4. Several factors apparently play a role in the remarkable protection which the normal human skin affords against bacterial invasion. However, these factors are by no means well understood, and further basic study of them will increase the effectiveness of methods of aiding the skin to resist damage from bacteria.

5. When the integrity of the human skin is disturbed, harmful bacteria readily become well established residents of the diseased area. In the management of cutaneous diseases which are characterized by inflammatory reaction, it is important to avoid the use of measures which may further irritate the skin and to recognize and treat bacterial invasion promptly.

6. The usefulness of topical penicillin therapy in the treatment of superficial infections of the skin is seriously jeopardized by an increased incidence of contact sensitivity which is being encountered. The present incidence of sensitivity reactions is apparently over 15 per cent, and this percentage may increase as more persons are exposed to the drug.

7. Superficial acute infections such as impetigo and ecthyma ordinarily respond promptly to local penicillin therapy. The responsible bacteria are not always removed rapidly, however, and continued care and observation for several days after apparent cure is necessary to prevent relapses.

8. The response of chronic cutaneous infections, or of chronic eczematous lesions in which there is an element of infection, to penicillin therapy is only moderately good.

9. Local application of sulfonamides to sites of superficial infection has little or no place in present day therapy. While the development of sensitivity in a significant proportion of patients can be prevented by using sulfonamide ointment only for primary acute superficial infections and for periods of not longer than five days, experience has shown that it is impossible to insure observation of these precautions in practice. Sulfonamides by mouth still retain a definite place in the management of certain acute and chronic infections of the skin and can ordinarily be given without severe reactions, provided that reasonable precautions are exercised.

10. While definite improvement in the methods of dealing with superficial bacterial infections of the skin has been achieved, these methods are susceptible of further improvement. In particular, the development of penicillin or sulfonamide compounds with a decreased capacity for sensitizing the skin and other tissues is needed. There is also need for nonsensitizing chemical antiseptics which have a greater antibacterial power in vivo than those now available.

Carcinoma of Lung.—While published statistics vary, the majority indicate that about 50 per cent of primary carcinomas involve either the upper middle or the lower lobe of the lung. Further, the cases that can be treated surgically usually are included in this group, since carcinoma of a main bronchus rarely is operable unless discovered in its incipience. Since from 30 to 40 per cent of cases occur beyond the range of vision of the bronchologist, these offer a direct challenge diagnostically, for they are the cases that more often must be diagnosed either by exploratory thoracotomy, aspiration biopsy or other means and frequently are not brought to a final conclusion diagnostically until other plans of diagnosis and therapy are tried and valuable time is lost.—Clerf, Louis H., and Herbut, Peter A.: Diagnosis of Bronchogenic Carcinoma by Examination of Bronchial Secretions, *Ann. Otol., Rhin. & Laryng.* **55:**646 (Sept.) 1946.

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association
and Hygeia, the Health Magazine
Chicago

(Continued from page 638)

(NOTE.—*Following are the second and third chapters of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of THE JOURNAL. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in THE JOURNAL. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—ED.)

CHAPTER 2. *The Organization of the American Medical Association*

On May 5, 1847 the delegates to the National Medical Convention met in the hall of the Academy of Natural Sciences in Philadelphia. Dr. Isaac Hays, chairman of the Committee on Arrangements from the Philadelphia delegation, welcomed the delegates to the city. He told them of the gratification afforded the Philadelphia physicians in receiving the members of the convention as their guests. He then proposed the name of Dr. Jonathan Knight of Connecticut as chairman. A credentials committee was established and also a nominating committee, which was instructed to nominate four vice presidents and three secretaries. Permanent officers of the convention included as president Dr. Jonathan Knight of Connecticut; vice presidents, Dr. Alexander H. Stevens of New York, Dr. George B. Wood of Pennsylvania, Dr. A. H. Buchanan of Tennessee and Dr. John Harrison of Louisiana. The three secretaries were Dr. Richard D. Arnold of Georgia, Dr. Alfred Stillé of Pennsylvania and Dr. F. Campbell Stewart of New York.

A number of resolutions were introduced asking for places in the convention for any members of the previous convention who had not been elected to the present one, "any medical gentlemen present from states not represented" and any ex-officers of medicine from various medical schools or any professors from abroad who happened to be in Philadelphia. All these resolutions were most properly defeated. Similar technics for "stacking" conventions are examples of the notorious evils in democratic procedure.

Then Dr. Hays called for the reading of the report of the committee appointed in 1846. This report was read and ordered to be printed, as were also the reports on registration of births, marriages and deaths.

At the evening session of the same day a report was read on the requirements of the degree of M.D., another report on preliminary education and a portion of the report of the committee to prepare a code of medical ethics. Still later came the report from the committee on nomenclature of diseases and then the adjournment.

On the following day, after the convention assembled, Dr. N. S. Davis offered a resolution for committees to record the indigenous medical botany of our country.

A controversy developed on the resolution which dealt with the union of teaching and licensing. Here majority and minority reports were presented. Then came reading of the resolutions previously introduced, with the adoption of the resolution on preliminary education. Invitations were presented to the convention for its 1848 meeting.

Just before adjournment of the morning session, the members having perhaps become somewhat prolix, Dr. Joel Hopkins of Maryland offered a resolution to the effect that "no gentleman shall be permitted to speak more than twice on the same proposition nor occupy more than fifteen minutes for speaking, without leave of the convention." This resolution was amended by changing fifteen minutes to ten minutes and then adopted.

PRELIMINARY EDUCATION

Worthy of special note was the resolution on preliminary education of the young man in the field of medicine. The resolution read as follows:

> *Resolved,* That this Convention earnestly recommends to the members of the medical profession throughout the United States, to satisfy themselves, either by personal inquiry or written certificate of competent persons, before receiving young men into their offices as students, that they are of good moral character and that they have acquired a good English education, a knowledge of natural philosophy and the elementary mathematical sciences, including geometry and algebra, and such an acquaintance, at least, with the Latin and Greek languages as will enable them to appreciate the technical language of medicine, and read and write prescriptions.
>
> *Resolved,* That this Convention also recommends to the members of the medical profession of the United States, when they have satisfied themselves that a young man possesses the qualifications specified in the preceding resolution, to give him a written certificate stating that fact, and recording also the date of his admission as a medical student, to be carried with him as a warrant for his reception into the medical college in which he may intend to pursue his studies.
>
> *Resolved,* That all the medical colleges in the United States be, and they are hereby recommended and requested to require such a certificate of every student of medicine applying for matriculation; and, when publishing their annual lists of graduates, to accompany the name of the graduate with the name and residence of his preceptor, the name of the latter being clearly and distinctly presented as certifying to the qualification of preliminary education.

Some of the members in the convention opposed this resolution, urging that it would prevent many young men of limited means from entering the medical profession whose natural endowments would carry them to the highest rank, notwithstanding their inadequate preliminary preparation. The argument was answered by the statement that "Our country provides school houses and almost unlimited facilities for acquiring a knowledge of at least the ordinary branches of learning." N. S. Davis said that "young men who had not mental energy and perseverence enough to comply with the standard proposed in the resolutions, certainly had not enough to enable them to do justice to a profession as extensive, intricate and arduous as ours."

These resolutions were adopted by nearly a unanimous vote and were then reaffirmed by almost every meeting of the Association that followed. They have, in fact, constituted a guiding principle in the field of medical education in this country for a hundred years. Subsequent resolutions urged lengthening of the curriculum from four months to six months, a minimum of three entire years to be devoted to the study of medicine, a minimum age of 21 for entering the practice of medicine, at least three months devoted to dissections, at least one session of hospital practice (which, to us, would mean an internship), and a method of making certain that students actually attended lectures.

CHAPTER 3. *A Permanent National Association*

Most important was the activity of the convention which resulted in the organization of a permanent national association. The committee reported in full a constitution designed to effect such a national organization. First came resolutions from the inspired physicians who thought that they had evolved better names than the one which was ultimately chosen. Thus one name considered was "The Conventional Association of the United States," another "The Medical Association of the United States of North America." Both these proposals were lost, after which the constitution developed by the committee was offered to the convention and accepted. It included the clause "This institution shall be known and distinguished by the name and title of 'The American Medical Association.' "

This constitution wisely proposed the principle of representation by making the acting members of the Association consist of delegates from medical societies and institutions in accordance with a fixed numerical ratio.

The preamble attached to the constitution declared the purpose of the organization to be "for cultivating and advancing medical knowledge; for elevating the standard of medical education; for promoting the usefulness, honor and interests of the medical profession; for enlightening and directing public opinion in regard to the duties, responsibilities and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those engaged in it."

The founding fathers urged the formation of state and local associations and so framed the constitution as to make the great majority of the members of the national association consist of delegates from permanently organized state and county medical societies throughout the nation. Thus from the very first the democratic principle prevailed.

Mindful, moreover, of the scientific aspects of the organization, committees were established on medical sciences, practical medicine, surgery, obstetrics, medical education, medical literature and publication.

The convention then resolved itself into the American Medical Association.

A committee consisting of one from each state represented was appointed to nominate officers for the ensuing year, and these were unanimously elected. The officers were:

President—Dr. Nathaniel Chapman, Pennsylvania.

Vice Presidents—Drs. Jonathan Knight, Connecticut; Alexander H. Stevens, New York; James Moultrie, South Carolina; A. H. Buchanan, Tennessee.

Secretaries—Drs. Alfred Stillé, Philadelphia; J. R. W. Dunbar, Baltimore.

Treasurer—Dr. Isaac Hays, Philadelphia.

Significant of this birth-giving meeting of May 7, 1847 were resolutions leading toward the preparation and ultimate adoption of the principles of ethics.

A resolution was offered requesting the Congress of the United States to allocate a portion of the funds of the Smithsonian Institution to uses of the American Medical Association, and that resolution was laid on the table. Dr. Austin Flint of New York presented a resolution urging the states to pass laws sanctioning and providing for the prosecution of dissections. That resolution was promptly and unanimously passed.

When Dr. Nathaniel Chapman was called to the chair, he spoke briefly but expressively:

> "He could find no language to express the depth of his gratitude. It had often been his good fortune during his professional life to have been complimented in the same manner, though not in the same degree. This was the most precious of all the honors he had received, as spontaneously conferred by his own brethren. He confessed his incompetence to serve the Association as he could desire. He loved his profession and should be ungrateful if he did not: whatever he possessed in this life had been bestowed by its favors; when he forgot it, or deserted it and its disciples, he remarked, with great emphasis, "may Almighty God forget and desert me." He desired that the Association should be persuaded of his ardent wishes for the cause, and that his most strenuous efforts would be unceasingly directed to advance the dignity of the profession and extend its usefulness.

QUACKERY

From the very first the American Medical Association has prosecuted its war on quackery and more than any other agency in our country can take the credit for the vast improvement that has occurred in the abolition of nostrums, secret medicines and quackery. At the session on May 7, 1847 Dr. John B. Johnson of Missouri introduced a resolution in which he pointed out that numerous and important evils result from the universal practice of allowing persons almost wholly ignorant to engage in apothecaries and still greater from the universal traffic in secret medicines. He urged that schools of pharmacy be established in the individual states and that some rule be adopted that no physician patronize a druggist or an apothecary who deals in "patent" or secret medicines.

The convention adjourned to meet in Baltimore on the first Tuesday in May 1848. Thus ended one of the most significant assemblages in the history of our nation. This was the birth of a great organization.

Dr. Nathan Smith Davis took great pride in the fact that the principle embodied in the first constitution made the national association emanate directly from local medical organizations and institutions. This system of representation gave the organization a legitimate claim to be truly representative of the whole medical profession. Indeed the representatives were so earnest in their desire to avoid dominance by any section in the work of the organization that they also incorporated in the constitution a provision which prohibited the holding of annual meetings twice in succession in the same place.

To recapitulate, the original plan of organization as adopted in 1847 provided that "members of the American Medical Association . . . should hold their appointment to membership either as delegates from local institutions, as members by invitation or as permanent members." There were thus created three classes of membership, of which the delegates constituted the bulk and the most important part. They received their appointment from "permanently organized societies, medical colleges, hospitals, lunatic asylums and other permanently organized medical institutions of good standing." Each appointment was for one year. The basis of representation was one delegate for every ten regular resident members of the medical society, two for every regularly constituted and chartered school of medicine, two for every hospital containing 100 inmates or more, and one for all permanently organized medical institutions of good standing not included in the foregoing summary. In order to admit of representation from portions of the United States not otherwise represented, provision was made for members by invitation. If a physician from sections of the country in which no medical institutions of any sort existed attended an annual session, the Association could constitute him a member by invitation for that session only. He thus became an unofficial delegate for a section that would otherwise be without representation. Thus two classes of members, both, as will be seen, of a purely temporary character and deriving their right of membership either from the organization which they represented or from the Association which invited them to a seat in its deliberations, constituted the voting membership of the American Medical Association. In order that delegates having once been members of the Association might retain some connection with it after their time as delegates had expired, it was provided that all those who had served in that capacity and such other members as might be appointed by the Association, by unanimous vote, might be made "permanent members." They were entitled to attend the meetings and to participate in the affairs of the Association without the right to vote. It was therefore recognized from the time of the first preliminary convention in 1846 that the right to vote should be limited to the duly elected and qualified delegates of local medical societies, colleges and hospitals who came bearing credentials of their election as such. Thus the American Medical Association was from the beginning a delegate body.

When its total membership reached as many as 60,000 members in the state societies, the assignment of one delegate for every ten members would have made a representative body of 6,000. This brought about ultimately the reorganization, of which more will be told later, and led finally to the formation of the House of Delegates of the American Medical Association as we know it today.

When William H. Welch was President of the Association in 1910 he called to mind the battle which took place in the originally constituted convention over the decision as to whether there should be a representative body or an organization in which the officers would themselves perpetuate the control within a small group.

"It is curious to think," said Dr. Welch, "what would have been the history of the Association had the choice not been made in favor of the more democratic representative plan."

This plan, which continued in operation for fifty-five years, was perhaps cumbersome and ineffective, but it was well suited to the conditions that existed at the time of its adoption.

Looking back at the first fifty years of life of the American Medical Association, William H. Welch noted that the founders brought into being a national organization truly representative. "Such an organization," he said, "has inherent elements of strength which secure its future even against its own blunders and still more against attacks from without. The Association has been from the beginning the great unifying force for the profession of this country, whose common interests it has been its chief endeavor to serve."

In concluding his address, William H. Welch said:

> Organized effort is a distinguishing mark of modern civilization. It is as essential for the advancement of science, of education, of social and industrial reform, of philanthropic endeavor as for the promotion of commerce. With the remarkable progress of medical science, especially during the last three decades, man's power to control disease has been vastly increased and the sphere of usefulness of the physician has been correspondingly widened and with advancing knowledge will continue to expand. The skill and knowledge of the physician and sanitarian have acquired a new and ever increasing importance and significance in the movements for social amelioration, for improvement of the conditions of labor and of living, for the conservation and most efficient utilization of the productive energy of the world, and for the reclamation of regions now yielding no return to civilization.
>
> Among the organized forces for advancing the prosperity, the happiness and the well being of the people of this country, the American Medical Association has an important part to play. We are justified in the confidence that, with the united support and loyalty of the profession, this Association, broadly representative and standing for the best ideals of medical science and art and for professional and civic righteousness, will contribute a beneficent share to the working out of our national destiny.

(To be continued)

Clinical Notes, Suggestions and New Instruments

NEW TREATMENT FOR INCOMPETENT VALVES IN VARICOSE VEINS

GERALD H. PRATT, M.D.
New York

In several reports published in the last ten years I have discussed the problem of treating varicose veins.[1] The large number of patients who are disabled from the complication of pathologic changes in the veins of the lower extremities makes this problem increasingly important.

The technic of resecting a section of the saphenous vein and its branches at the femoral junction is well standardized.[1a] The necessity of an adequate resection to divide any connection between the superficial and the femoral system high in the groin without leaving a saphenous stump requires continued emphasis. Approximately one fourth of all my new patients have had a ligation previously, and in all but 2 of these patients on whom I have reoperated in the last year either a large saphenous vein or a dilated branch acting as a saphenous vein has been found in the groin.

When an adequate high resection has been performed, recurrent veins, venous ulcers and other complications are the result either of failure to resect the incompetent communicating branch points at the correct juncture or of the development of new incompetent points. In 1941 a simple test for determining these incompetent points was presented.[1c] This test has proved

M. A. **122**: 797-800 (July 17) 1943.

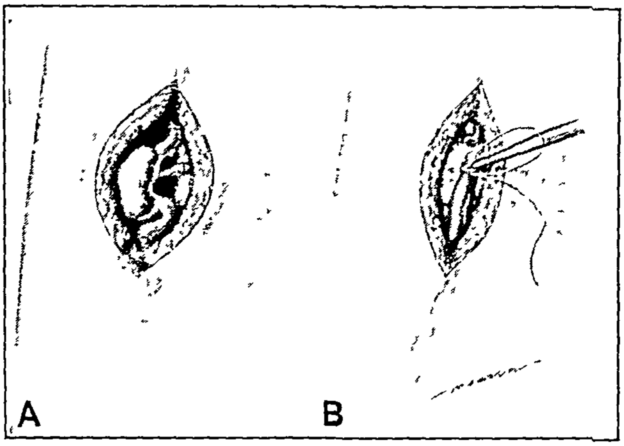
entirely satisfactory in over 3,000 instances in both civilian and naval hospital experience and has replaced all other methods of deciding the points for resection. This test should be performed and the marking of the point should be done in the operating room just before the operation. On the average, three such incompetent points are resected.

Where incompetent valves permit femoral reflux to the superficial veins, these veins become dilated and tortuous. Because of their weight and the resultant edema, the soft tissues sag and become soft and relaxed. Noting the excellent results obtained in the treatment of varicoceles by suturing the ends of the veins together and thus suspending the resected ends, a somewhat analogous measure has been instituted after the removal of the so-called "blowout" points. After the "blowout" is resected and the feeding or T-shaped veins divided and tied off, the distal end is transfixed and sutured on tension to the deep fascia. This stretches the tortuous distal end and lifts and suspends the spongy soft tissues. The distal veins become a fibrous band which is attached to the deep tissues, and this acts as a fibrous lift to the tissues. Since in most instances the involved vein is a feeder to an ulcerous or preulcerous area at or above the inner malleolus, the tendency to ulceration is decreased. *The movement of the deep fascia keeps the vein* tight, empties the branches and aids its fibrosis. The physical appearance of the ankle is improved at once



A in the illustration, resection of incompetent communicating vein with suspension of distal end. *B*, T-shaped incompetent point resected; distal end transfixed and sutured to deep fascia.

This procedure now has been followed in all instances for the last year in civilian practice and for the preceding year in the Navy, and the improvement in the condition of these legs is apparent to all observers. This is true especially when there are ulcers present. The healing time is reduced and the attendant edema and dermatitis decrease more rapidly.

No one measure can ever be the answer to the problem of varicose veins. Elimination of all incompetent valves is paramount in importance, but this does not resolve the whole problem. The fungous infection which is nearly always present needs control, and in my practice this responds best to soaks with potassium permanganate solution in 1:5,000 strength every second or third day. Elevation and adequate support with guided walking exercise is also helpful. Since these patients have defective valves or pathologic changes in the vein wall they will need observation from time to time. As do patients with defective teeth or with pulmonary problems, they should have a check-up examination at regular intervals. An occasional dilated vein may appear and require an injection. If incompetent connections between the femoral and the saphenous system are not present this is effective. A new incompetent point may need a local resection later.

In addition to this program, it is now suggested that the surgical suspension of the distal end of "blowout" veins will help in the control of this difficult and widespread condition. The suspension can be performed likewise in the thigh or groin when dilated tortuous veins show that it is indicated.

30 East Sixtieth Street.

Council on Pharmacy and Chemistry

REPORT TO THE COUNCIL ON PHARMACY AND CHEMISTRY

The office of the Council on Pharmacy and Chemistry and other offices at the headquarters of the American Medical Association have been receiving an increasing number of inquiries on drugs that have been used and proposed for the relief and control of asthma and allergy in general. There has been an unfortunate amount of publicity given to certain aspects of this subject, and confusion has resulted. To dispel the confusion and present the medical profession with a comprehensive review of the newer aspects of drug therapy, a report has been prepared by Dr. Samuel M. Feinberg. The Council expresses its appreciation of the cooperation shown by Dr. Feinberg. It hopes that its offices will be freely used by members of the medical and allied professions who have further inquiries concerning the availability and usefulness of the articles described in the following presentation and of other drugs that may be available but not discussed in the report by Dr. Feinberg.

Austin Smith, M.D., *Secretary.*

HISTAMINE AND ANTIHISTAMINIC AGENTS

Their Experimental and Therapeutic Status

SAMUEL M. FEINBERG, M.D.
Chicago

The demonstration of the phenomena of anaphylaxis, which had its impetus at the turn of this century, was largely responsible for the progress in the development of an understanding of the allergic diseases. First, attention was directed to the fact that the clinical symptoms of such conditions as asthma and hay fever resembled closely the anaphylactic symptoms in the guinea pig. Then, in rapid order, it was shown that the principles of active and passive sensitization, desensitization, demonstration of tests for specific sensitivity and the presence of transferable antibodies were applicable to both anaphylaxis and allergy. Particularly the phenomenon of desensitization in anaphylaxis—the production of a refractory state by frequent small injections of the antigen—was welcomed and applied to the therapy of allergic conditions.

No sooner had specific desensitization been demonstrated than experimenters began to turn their energies to find a method which would desensitize, or inhibit anaphylaxis, without the employment of a specific antigen. Such nonspecific antianaphylaxis would become an extremely useful tool not only experimentally but, conceivably, also clinically. Up to 1932, at least one hundred and sixty-five substances or methods[1] aiming at nonspecific inhibition of anaphylaxis had been reported. Among these may be mentioned barium sulfate, barium chloride, atropine, ether, chloral hydrate, nonspecific serums and proteins, desensitization with a heterologous antigen, benzene in large doses, heparin, intercurrent infection with Mycobacterium tuberculosis and reduction in barometric pressure. Although some of these methods possessed a certain degree of merit, on the whole they were impractical, too hazardous or insufficiently effective.

In recent years many additional methods aiming at nonspecific inhibition of anaphylactic shock and allergic manifestations have been proposed.[2] For the most part, these claims are negative, of doubtful value or not properly corroborated. For example: barbital, pernoston and tribromoethanol were claimed[3] to produce reduction in anaphylaxis, but the effective doses of these drugs were so toxic as to be frequently fatal. The use and abuse of potassium salts and sodium thiosulfate in the treatment of allergic manifestations led to their experimental trial by Carlson and Whitehead[4] in anaphylactic shock with negative results. According to Hofmann,[5] ascorbic acid (vitamin C) injected into guinea pigs prior to the anaphylactic dose of the antigen reduced the mortality rate to one half. Many other workers, however, failed to confirm a protective effect. The value of ascorbic acid in the therapy of allergic conditions has been disappointing[6] The claimed benefit of hesperidin (vitamin P) in anaphylaxis[7] requires corroboration. Ethylene disulfonate (Allergosil), which has been so widely publicized in the treatment of allergy, has been found therapeutically ineffective by a committee of specialists[8] and ineffective in the inhibition of anaphylaxis.[9]

HISTAMINE—ITS ROLE IN THE MECHANISM OF ANAPHYLAXIS AND ALLERGY

From the very beginning of observations in anaphylaxis and in allergy it has been evident that even though a specific antigen is required for the production of the reaction in the individual case, the manifestations produced do not differ from those induced by different antigens. It has seemed from the start, therefore, that one substance common to all anaphylactic reactions might be responsible for the manifestations In 1910, Dale and Laidlaw[10] pointed out the similarity of manifestations in the effect of histamine and in anaphylactic shock. This constituted the starting point for the progression of experimental evidence incriminating histamine as the mediator of anaphylactic symptoms. Best and his associates,[11] in 1927, demonstrated the presence of histamine as a normal constituent of many tissues and thus furnished a reasonable explanation for the source of the histamine in anaphylaxis. At about this time it was also becoming evident that the variation in the anaphylactic manifestations in different species of animals could be reasonably explained on the basis of quantitative differences in histamine content. Later it was shown[12] that the lungs of guinea pigs and the livers of dogs were decidedly reduced in histamine content after anaphylactic shock. Subsequently a histamine-like substance was demonstrated[13] in the blood and thoracic duct lymph of the dog during anaphylaxis, and a similar substance was found[14] in the blood of the guinea pig.

When the amounts of histamine found in the anaphylactic dog in the blood of the inferior vena cava just above the diaphragm were observed to be similar to those amounts required to produce the same vascular changes by intravenous injection, Dragstedt and Mead[15] were able to complete the case for histamine as an important factor in the production of the manifestations of anaphylaxis It was subsequently shown by Code[16] that 70 to 100 per cent of the normal blood histamine of man, horse, goat, calf, dog, bullock and guinea pig was in the white cells.

There is no valid argument against the evidence that histamine constitutes a potent factor in the production of the symptoms of anaphylactic shock. There is justification for the assertion that not all the manifestations can be explained on the basis of histamine activity. One such outstanding phenomenon is the incoagulability of the blood. This has been satisfactorily accounted for by the demonstration of a release of heparin during anaphylaxis Other anaphylactic manifestations not attributable to histamine, and the mechanism of which is not properly explained, are the early increased blood coagulability, the leukopenia, changed sedimentation rate and the delayed death from anaphylactic shock occurring in some instances

The evidence for the role of histamine in the mechanism of production of allergic manifestations in man has not kept pace with that for anaphylaxis in animals. A good part of the evidence in favor of the histamine concept of allergy is based on the demonstration of the various points of resemblance between allergic and anaphylactic reactions, and on the fact that the effects of histamine administered to man are consistent with some of the phenomena of allergy. It was shown by Lewis and Grant[17] and others that the whealing of dermographism, or urticaria factitia, and of specific food allergy had all the characteristics of histamine wheals. Subsequently it was demonstrated[18] that the manifestations of hypersensitiveness to cold—a drop in blood pressure and an increase in pulse rate, gastric acidity and skin temperature—were those resembling the action of histamine.

Although there is some indication that there is an increased level of histamine in the blood in allergic reactions,[19] the amounts involved and the difficulties in technic have not permitted conclusive proof of this point. Recent improvements of the methods used in isolating the blood histamine and new methods of quantitatively measuring it may give much more satisfactory data. The fact that the histamine in the leukocytes is released from the blood in vitro by the addition of the specific allergen [20] not only is a further demonstration of the role of histamine in allergic reactions, but it points toward many further possibilities of studying the mechanism of allergy. It has been shown [21] further that histamine can be released from the skin by the application of the specific agent.

HISTAMINE THERAPY AND TOLERANCE

On the basis of the presumed role of histamine in the mechanism of allergy and on the supposition that a tolerance to histamine could be obtained by repeated administration of this agent, many clinicians were influenced to undertake histamine therapy in allergic diseases. Ramirez and St. George [22] in 1924 reported their observations in a group of patients with "endogenous" asthma. They believed that this group owed their difficulties to the fact that they were more sensitive to histamine than were other persons. They treated 10 patients with increasing doses of histamine and obtained temporary good results in 2. In 1935, Dzsinich [23] claimed good therapeutic results with small doses of histamine in a series of patients with asthma and urticaria. It has also been claimed by Farmer [24] that effective results may be obtained in asthma and vasomotor rhinitis by frequently repeated small doses of histamine.

A series of injections of histamine was claimed by Millet [25] to produce favorable results in angioneurotic edema. Ernestene and Banks [26] treated a group of 13 patients with pruritus, urticaria and angioneurotic edema, using 0.5 mg. doses of histamine, at first twice a day, then less frequently. They reported improvement in half the cases, although recurrences were present. In spite of the claimed results the authors stated that "no evidence of diminished sensitivity to histamine was observed in our patients."

In 1927, Friedlaender and Petow [27] described good results in a series of cases of migraine with the administration of small doses of histamine (0.01 to 0.001 mg.) every two days. Horton and his associates [28] in 1939 described the syndrome of "erythromelalgia of the head" in 84 patients. This consisted of periodic attacks of simple migraine, with the following manifestations on the affected side: swelling of the temporal vessels, flushing and increased temperature of the skin, engorgement of the soft tissues of the eye and watering of the eye and nose. These authors regarded this type of headache as due to the release of histamine. They claimed to reproduce the syndrome in these persons by the injection of 0.3 to 0.5 mg. of histamine. The patients were treated by subcutaneous injections of the substance. The reports resulted in a fairly extensive trial of histamine in various types of headache. One of the most recent reports is that of Butler and Thomas,[29] who claimed that excellent results were obtained in a series of patients with migraine by the intravenous administration of histamine.

Attempts to demonstrate that histamine tolerance can be achieved have been inconclusive. Farmer [30] attempted to prove that the oral and parenteral administration of histamine influenced the sensitivity of the uterine strip of the guinea pig to histamine and to the specific antigen. From the standpoint of the usual range of variations in the results of such experiments, his data cannot be regarded as impressive. Karady [31] has also presented evidence favoring histamine tolerance. She found that pretreatment with histamine in guinea pigs caused increased tolerance to the activity of histamine amounting to 100 per cent. Anaphylactic death in guinea pigs sensitized to horse serum could be prevented in the majority by pretreatment with histamine, while in sensitivity to the whites of eggs pretreatment with histamine had no influence on anaphylactic shock. Such varying results make the entire report of doubtful value. Clark and MacKay [32] gave daily injections of histamine for two weeks to a series of guinea pigs: they were not able to show the development of a tolerance to histamine. Mayer, in the course of experimenting with anatagonists to histamine, observed that repeated inhalations of histamine did not cause increased tolerance. Wells, Gray and Dragstedt,[33] working with dogs, found in a large series of trials that there was no evidence of tolerance or desensitization induced as a result of repeated injections of histamine.

Attention should be called to the fact that there is a wide range of sensitivity to histamine in different persons and that there is a lack of real evidence that the variations are greater among allergic than among nonallergic persons. There is not a sound basis for the belief that allergic manifestations are produced because of a heightened sensitivity to histamine. If histamine has to do with the allergic reaction it is because an amount above the tolerance dose is released from the tissues. Repeated observations over many years lead me to believe that injections of histamine in man do not increase his tolerance, that each individual has his own particular reactive dose, and that this dose is not affected by treatment with histamine. Furthermore, even if it were granted that in animals or man the tolerance to histamine could be increased twofold or threefold by such treatment, such protection could not suffice for the conditions encountered in anaphylaxis and allergic reactions. From my experience and from that of others it is felt that the effectiveness of histamine in allergic conditions has been exaggerated, and that whatever beneficial results are obtained must be explained on a basis other than desensitization to histamine.

HISTAMINE-AZOPROTEIN

Since unbound histamine failed to produce antibodies to itself after its parenteral administration, it was thought by Fell and his associates[34] that a histamine conjugate might be more effective in the stimulation of antibodies to histamine. By means of azo linkage, they coupled histamine to various proteins such as casein, horse serum globulin, cow serum globulin and dog serum. In precipitin tests on rabbits' blood they found that the specificity had been partly determined by the hapten portion (histamine). However, the precipitin titer for the protein fraction was fully as high. In a series of guinea pigs sensitized to ovalbumin and showing a mortality rate of 52 per cent from anaphylactic shock, pretreatment with histamine-azo-despeciated horse serum globulin diminished the mortality rate to 8 per cent. Other types of immunologic experiments also indicated that animals treated with histamine conjugate antigens developed antibodies that were partially specific for the histamine hapten.

Sheldon and his associates[35] in 1941 reported their results of treatment with histamine-azoprotein in a series of 39 patients. The duration of treatment varied from 1 to 20 months, and the highest dosage of the solution ranged from 0.1 to 1.0 cc. of a 1 : 10 antigen. Of 17 patients with atopic or contact dermatitis, 8 had either excellent or good results. Of 22 patients with asthma, rhinitis, urticaria and other allergic manifestations, excellent results were obtained in 10 Cohen[36] claimed to have obtained good clinical results, but presented no statistical data in substantiation.

In sampling the clinical experience of allergists, the Committee on Pharmaceuticals and Medicaments of the American Academy of Allergy obtained information which indicates that those who have given the histamine-azoprotein a fair trial either have found it totally ineffective or have been able to attribute whatever measure of effectiveness it had to its nonspecific action. My own personal experience has been in agreement with that of the majority of other allergists. Although I began to use this substance over five years ago, I have seen only occasional benefit in allergic conditions.

In 1943, Cohen and Friedman[37] presented data in support of the claim that histamine-azoprotein injections in man developed precipitins and antibodies capable of neutralizing histamine. Insufficient controls and irregularity of the results make the value of these observations open to doubt. Cohen and Friedman[38] also showed that allergic patients treated with histamine-azoprotein displayed a heightened tolerance to histamine by iontophoresis as compared with a normal group of subjects However, figures were not presented for the histamine tolerance of these allergic patients prior to treatment with the histamine conjugate. In a recent report Cohen and Friedman[39] stated that the degree of immunity afforded by this treatment is not great, but they believed that it serves as an adjunct in well managed cases of allergy. Hebald and his associates[40] failed to obtain a protective action against constitutional reactions from moderate ragweed overdosage by pretreatment with histamine-azoprotein. Dundy and his collaborators[41] could not obtain any change in whealing responses or in the clinical conditions of allergic patients.

A recent paper by Coffin and Kabat[42] may throw light on the general confusion of the status of this compound. They conducted experiments to determine the effect of treatment with histamine-azoprotein on histamine tolerance and on anaphylaxis in the guinea pig. Pretreatment with histamine-azoprotein did not have a significant influence on the mortality rate from the minimum lethal dose of histamine given intravenously. Passively sensitized animals pretreated with histamine-azoprotein, either alum-precipitated or with adjuvants, displayed a definite protection against anaphylaxis. However, animals pretreated with human serum and adjuvants showed similarly striking anti-anaphylactic capacities.

It would seem that this whole subject of protection against anaphylaxis and histamine needs a more careful reevaluation.

HISTAMINASE

In 1929 Best[43] demonstrated that some of the tissues contain a substance or enzyme capable of destroying histamine The ability of this histaminase to destroy histamine when the two are mixed and incubated was confirmed by many workers. It was only natural that much hope should have been raised in the expectation that an antihistaminic and an antiallergic substance had been found which would be effective in allergic conditions. Many experimenters soon discovered that although histaminase does destroy histamine under ideal conditions in vitro, it lacked an effect on histamine or anaphylaxis in the living animal

A case of hypersensitiveness to cold was claimed by Roth and Horton[44] in 1937 to have responded to therapy with histaminase. In 1939, Foshay and Hagebusch[45] claimed effective results from the use of this medicament in serum sickness. This was followed by widespread use of histaminase and by a number of favorable clinical observations, such as those in vasomotor rhinitis,[46] hay fever,[47] insulin allergy,[48] urticaria,[49] dermatoses[50] and almost all allergic manifestations.[51]

Concomitantly with the above claims there began to appear reports from clinicians having extensive experience with allergic manifestations and their evaluation. Toomey and Kriete[52] found that histaminase caused neither prevention nor amelioration of serum sickness Eger and Stone,[53] administering the drug orally throughout the course of serum sickness in a series of patients, failed to observe a difference in the severity or duration of their symptoms as compared with those of an untreated group. In a series of hay fever patients Keeney[54] observed no benefit. Miller and Piness[55] failed to obtain results in any cases of hay fever, asthma or atopic dermatitis. Benefit was not obtained in a series of 48 children with various types of allergy by Peshkin and his associates.[56] Frank and Harris[57] found histaminase ineffective against asthma, vasomotor rhinitis and urticaria. In 1940 Alexander[58] concluded that the results of histaminase therapy were disappointing, although he felt that further investigation was warranted. My own clinical experiences with histaminase dating back nearly ten years indicate that it lacks a specific effect in allergic conditions. Best, the discoverer of histaminase, was finally moved in 1940, together with McHenry,[59] to make the following statement: "Our investigations over a period of 10 years have failed to show that the intravenous or intramuscular administration of histaminase has any effect upon histamine present in the body or on that given by injection. . . . For some years we have consistently answered numerous inquiries about histaminase with the statement that we believed there was no physiological basis on which to rest its clinical use."

The Council on Pharmacy and Chemistry of the American Medical Association[60] in 1940 issued a report stating that histaminase and the brand Torantil did not show sufficient evidence of clinical worth to justify its inclusion in N. N. R.

There is considerable evidence that histaminase does not modify the whealing reactions in man In a cold-sensitive patient Maisel and Abramson[61] made careful studies of the measurements of whealing produced by a standard cold stimulus: prolonged treatment with histaminase did not produce changes in the size of the wheal or in its rate of formation. Keeney[54] failed to obtain change in the histamine wheals in hay fever subjects who were treated with histaminase. Miller and his associates[62] demonstrated that the oral or parenteral use of histaminase did not have influence on the reactions of the skin to dilutions of histamine or on the sensitivity of passively sensitized sites to an allergen Change in the size of histamine wheals was not observed by Knoll and Beinhauer[49b] in 50 nonallergic subjects after prolonged administration of histaminase. Vaughan and Blanton[63] also failed to obtain changes in histamine whealing. Simon[64] showed, further, that the injection of histaminase locally did not influence either the histamine wheal or the wheal produced by a specific allergen in a passively sensitized site. In a study of 36 allergic patients, Rose[65] found that the administration of histaminase did not alter the blood histamine levels.

The claim of Karady and Browne[66] in 1939 that histaminase was effective in the prevention of histamine and anaphylactic shock led many other workers to reinvestigate this subject. Alexander and Bottom,[67] Youngener and his associates[68] and Rose and Browne[69] failed to prevent histamine shock in guinea pigs by the administration of histaminase. That histaminase is ineffective in the prevention of anaphylactic shock was demonstrated by the reports of Courtright and his associates,[70] Hawes and his co-workers[71] and Barlow and Homburger.[72] The experimental asthma produced in guinea pigs by the inhalation of an atomized antigen was not influenced by histaminase, according to Neeley.[73]

SYMPATHOMIMETIC DRUGS

It is not the purpose of this paper to discuss the entire range of drugs employed in the therapy of allergic manifestations. The only object in mentioning the sympathomimetic drugs at this juncture is to point out the difference in the mechanism of their action as compared with that of the antihistaminic agents. Epinephrine, ephedrine, Propadrine hydrochloride and similar drugs owe their antiallergic action primarily to the vasoconstriction they produce. They apparently have no appreciable action on the immunologic or chemical mechanism involved in the allergic reaction. It is important to realize this for several reasons, including the limitations of their action and the fact that they do not interfere with the concomitant use of antihistaminic agents.

EARLY ANTIHISTAMINIC AGENTS

The realization that histamine plays an important part in the anaphylactic and allergic reaction has led to considerable effort to discover a means of combating this substance. Almost all the proposed methods which showed any appreciable degree of promise have had in common the characteristic of competitive action, i. e., their activity is due to competitive attachment to the cell receptor, thus displacing or replacing histamine.

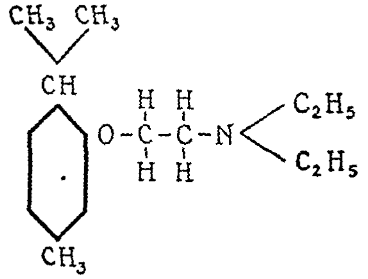
The amino acids, histidine, cysteine and arginine were shown to have histamine-inhibiting properties. In 1937, Edlbacher and his associates [74] showed that these substances inhibited the contraction of the guinea pig intestine produced by histamine Arginine was then found to inhibit the contraction of the sensitized guinea pig intestine [75] and to prevent anaphylactic shock [76] The antihistaminic action of histidine was corroborated by the work of Mackay [77] and Halpern [78] The behavior of the amino acids was recently reinvestigated by Landau and Gay.[79] In the main, these workers corroborated the results obtained by the earlier investigators, but they pointed out that not all histamine symptoms could be prevented and that effective doses of arginine would cause a high incidence of fatal toxic reactions They did not discover evidence of inhibition of anaphylactic shock by arginine. A 2 per cent arginine solution given intracutaneously in man failed to affect the pollen reaction either when injected into the wheal or when combined with the pollen There has been general agreement that the amino acids are not sufficiently active agents, and that they are too toxic for animals and man

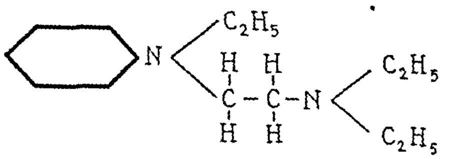
In 1933 Fourneau and Bovet [80] demonstrated that certain phenolic ethers have the property of counteracting the action of histamine in vivo and in vitro This constituted the starting point for the development of the subject of modern antihistaminic drugs. Fourneau and Bovet found the most effective of their phenolic ethers to be:



2 isopropyl 5 methylphenoxyethyldiethylamine
(thymoxyethyldiethylamine or compound 929 F)

Bovet and Maderini [81] demonstrated that this substance has an ergotoxine-like effect on the reversal of the pressor action of epinephrine. In 1937 Staub and Bovet [82] described the antianaphylactic properties of this drug. The compound was found to protect guinea pigs against two lethal doses of histamine, but it produced well defined toxic effects in the animals.[83] Climenko and his associates [83] did not regard this drug as truly antihistaminic because they found that it was able to prevent the uterine horn contractions of barium chloride and acethylcholine. Rosenthal and Brown,[84] however, ascribed a selective antihistaminic action to this drug. A local anesthetic action was found to be another property of this substance. Rosenthal and Minard [85] cited this action in support of their contention that the sensation of cutaneous pain is the result of a local liberation of histamine

The great toxicity of the phenolic ethers led Staub [86] to turn her attention to another series of Fourneau compounds having the ethylenediamine radical. Of the group she studied the most promising was:



N phenyl N ethyl N′ diethylethylenediamine or compound 1571 F

Compound 1571 F was antihistaminic and antianaphylactic and, according to Staub, had no effect on the cutaneous reaction to histamine. Among others, Wilcox and Seegal [87] studied this compound. By prior administration of 1 to 4 mg. of the drug to guinea pigs they obtained protection against two to six minimal lethal doses of histamine The animals, however, showed pronounced toxic effects from the antagonist. Sensitized guinea pigs were fairly well protected against anaphylactic shock. The decreased coronary flow in the perfused heart of the guinea pig, due to the addition of histamine or the specific antigen was prevented by adding compound 1571 F to the perfusion fluid. The effect of compounds 929 F and 1571 F on gastric response to histamine or on food ingestion in dogs varies with the experimenters.[88]

From the experimental and preliminary clinical trial of compounds 929 F and 1571 F it was concluded that their toxicity was too great to warrant their use therapeutically

RECENT FRENCH ANTIHISTAMINIC DRUGS
(MOSNIER COMPOUNDS)

In 1942 Halpern [89] described his experimental observations with two of the most promising of a new series of compounds prepared by M Mosnier in the chemical laboratories of the Rhone-Poulenc Society of Chemical Manufacturing. These were:

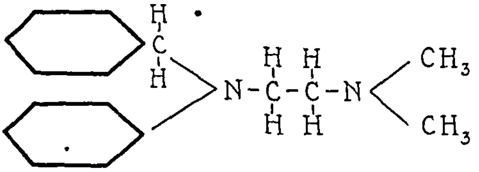
N'phenyl N'ethyl N dimethylethylenediamine
(dimethylaminoethylaniline or compound 2325 RP)

and



N'phenyl N'benzyl N dimethylethylenediamine
(dimethylaminoethylbenzylaniline, "Antergan" or compound 2339 RP)

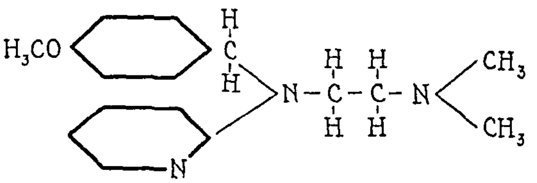
As will be noted, compound 2325 RP differs from 1571 F only in the substitution of a dimethyl for a diethyl group, while compound 2339 RP differs from 2325 RP in the substitution of a benzyl for the ethyl group.

Compound 2339 RP (Antergan) was found to be the more desirable, and Halpern concentrated his studies mainly on this drug. He found that shock and death from intravenous histamine and anaphylaxis could be prevented in the guinea pig by the previous administration of Antergan. The addition of small amounts of this drug to the bath prevented the histamine contraction of the intestinal strip of the guinea pig. Its comparative efficiency in such activity was as follows: 1571 F —0 1; 2325 RP —1 0; 2339 RP —15. In vitro contraction of the sensitized intestinal strip could be prevented either by the addition of the drug to the bath or by its administration to the intact animal While Antergan had a slight inhibiting effect on the activity of acetylcholine or barium chloride its effect was much greater against histamine.

The administration of 1 mg of Antergan per kilogram of body weight hypodermically prevented asthma in guinea pigs from aerosol histamine In such action this compound was not only more effective than the other histamine anatagonists studied up to that time but considerably more effective than ephedrine or atropine. Epinephrine was most active, but its toxicity hampered its efficiency In guinea pigs the LD-50 of Antergan (the dosage fatal to 50 per cent of the animals) was 175 mg per kilogram of body weight hypodermically and 300 mg. orally Toxic doses resulted in excitation and convulsions

The results of therapeutic trials of Antergan began to appear in the European literature in 1942 Gaté and her co-workers[90] described favorable effects in a series of cases comprising urticaria, eczema, hay fever, perennial rhinitis, migraine, asthma, dermatitis medicamentosa and anal and vulvar pruritus. Good results against hay fever were emphasized by Sciclounoff and Junet,[91] but their results against asthma were not as good. Aubertin[92] stressed the efficacy of the drug in the urticarial dermatoses. Satisfactory results were also reported by others.[93] The daily intake of the drug varied from 200 to 1,500 mg. Parrot,[94] as well as others,[91] showed that the ingestion of large doses of Antergan inhibited the cutaneous whealing from histamine.

More recently a new ethylenediamine derivative was described by Bovet and his associates.[95] This is:



N p methoxybenzyl N dimethylaminoethyl α aminopyridine
(Neoantergan or compound 2786 RP)

This compound is claimed to be more effective and less toxic than Antergan In guinea pigs a dose of 0.1 mg. per kilogram of body weight prevented death from five to ten lethal intravenous doses of histamine, while a dose of 1 mg per kilogram of body weight protected against seventy-five lethal doses of histamine. The contraction of the intestinal strip produced by 1 to 10,000,000 dilutions of histamine was abolished by 1 to 100,000,000 dilutions of Neoantergan. The capillary permeability of the dog as the result of histamine was decidedly attenuated by this compound.[96] It is claimed by Decourt[97] that Neoantergan is more effective and less toxic than Antergan clinically, but according to a personal communication from Halpern, its advantage over Antergan clinically is based more on the fact that it may be better tolerated rather than that it is more active

The experience of my associates and me with Neoantergan is as follows In guinea pigs it was highly effective in the prevention of death from histamine and anaphylactic shock In seasonal hay fever[98] the drug was of benefit to 39 of 60 patients (65 per cent), in perennial vasomotor rhinitis to 8 of 10 patients, and in asthma to 1 of 5 patients.

Recently, Halpern[99] has claimed that in experiments with another new compound he has been able to protect against twelve hundred to fifteen hundred lethal doses of histamine

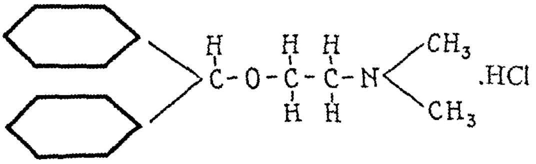
NEW AMERICAN HISTAMINE ANTAGONISTS

In the last few years intensive research has been conducted in pharmaceutical laboratories in this country in the attempt to find an effective and safe histamine antagonist for clinical use. As a result of this research two compounds have been made available for experimental and clinical trial. The experimental and therapeutic experience with these drugs by a number of workers, including me, will be described here. It should be kept in mind, however, that these products are not necessarily the final ones of their kind and that pharmaceutical institutions are continuing their quest for more potent and less toxic drugs.

BETA-DIMETHYLAMINOETHYL BENZOHYDRYL ETHER HYDROCHLORIDE (BENADRYL HYDROCHLORIDE)

This compound has the structural formula:



According to Loew and his associates,[100] Benadryl is two to four times more effective than compounds 929 F and 1571 F in preventing the death of guinea pigs from the inhalation of histamine. It was also effective in preventing death from histamine which was administered intravenously. In its antianaphylactic activity it was found at least as active as compound 1571 F. Wells and his co-workers [101] demonstrated that the activity of this histamine antagonist is directed to only a portion of the histamine. The injection of 10 mg. per kilogram of body weight of Benadryl in the dog prevented fatal anaphylactic shock and fatal histamine shock due to the injection of histamine in amounts comparable to those liberated from the liver in anaphylaxis.[102] This finding was advanced as an additional argument that histamine liberation plays a dominant role in anaphylactic shock.

Whealing.—One of the first questions that presented itself was: What effect does this drug have on histamine wheals? And if any diminution of the wheal occurs, does it have a similar action on the antigen-antibody wheal? Although the ingestion of 50 to 100 mg. of the drug resulted in the disappearance or diminution in the whealing of a series of patients with dermographism, the incidence of specific reactions with antigens by scratch tests indicated that there was a lack of practical interference with the antigen wheal.[103] Subsequently it was shown that [104] the oral use of the drug did not have any decisive effect on the whealing produced on scratch tests with serial dilutions of histamine or with ragweed extract in sensitive patients. When a solution of Benadryl was mixed with the histamine or ragweed extract, or when it was applied to scratches prior to the application of these wheal-producing agents, there was a dramatic inhibition of the whealing phenomenon.[104] Other whealing, such as that due to codeine, morphine, atropine, pilocarpine, bee venom and physostigmine, was also inhibited.[105]

Urticaria.—Urticaria and angioneurotic edema were the first manifestations reported to be relieved by this drug.[106] Friedlaender and I [107] found it to be effective in the urticarial dermatoses, as well as in dermographism, in the majority of patients treated. The good results in urticaria are confirmed by a number of workers.[108] The percentage of effective results varies somewhat with different authors, but all agree that about 80 per cent of the patients are benefited. The itching is almost always relieved, while the lesions are kept in abeyance in the majority of patients, although those in a few, particularly when the swellings have been of unusual size, may not be helped. The serum sickness type of reaction, particularly that following penicillin administration and consisting primarily of urticaria, itching and arthralgia, has been benefited in most instances except for the fact that the arthralgia has been more resistant. It should be emphasized that in the cases of urticarial and "serum sickness" reactions the relief was apparent for only a few hours following each dose of the medicament and that the final course of the ailment was in no way shortened or affected by this therapy.

Dermatitis.—In acute and chronic atopic dermatitis (flexural dermatitis, neurodermatitis) relief was noted from the itching in 20 out of 25 cases.[104] Other investigators have also observed such benefit.[108f,g] While the relief was directed primarily to combating the itching, the prevention of traumatization of the skin from scratching frequently resulted in salutary effects on the inflammatory process. In contact dermatitis the results were less striking. Pronounced relief of the itching of pruritus vulvae has also been noted.[101]

Hay Fever and Vasomotor Rhinitis.—In cases of hay fever, Koelsche and his associates [109] obtained relief in 75 per cent; Logan,[108d] in 75 per cent; Eyermann,[108e] in 67 per cent; Waldbott,[108f] in 74 per cent, and Levin,[108g] in 59 per cent. McElin and Horton [108b] also described benefit in hay fever, while A. Friedlaender[108a] observed but little benefit. The results in perennial vasomotor rhinitis were described by several workers.[110] The percentage of those benefited, where stated, varied from 28 to 85. In my own series[111] of 47 cases of perennial vasomotor rhinitis, symptomatic benefit was obtained in 7 (or 15 per cent), while 28 of 54 patients (52 per cent) with seasonal hay fever were helped. Logan and his associates[108d] claimed definite symptomatic improvement in 4 cases of hyperplastic ethmoiditis, with retraction and disappearance of the polypoid tissue and diminution or disappearance of the purulent discharge. The symptoms recurred, however, when the drug was discontinued.

[109] Koelsche, G A.; Prickman, L. E, and Carryer, H. M.: The Symptomatic Treatment of Bronchial Asthma and Hay Fever with B Dimethylaminoethyl Benzhydryl Ether Hydrochloride, J. Allergy **17:** 151 (May) 1946.

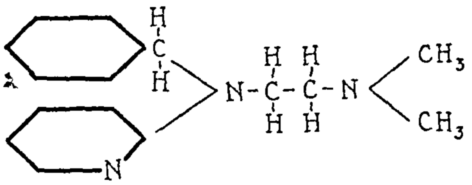
Asthma.—Asthma is not benefited materially by Benadryl, according to some observers.[112] On the other hand, Eyermann[108e] claimed good results in 65 per cent of his asthma cases; Waldbott,[108f] in 43 per cent, and Levin,[108g] in 65 per cent. Koelsche and his co-workers[109] observed that relief was obtained in a greater percentage of patients with seasonal cases than in those with perennial cases. In my series of 50 cases of asthma, mainly of perennial etiology, definite relief of symptoms was observed in only 12 per cent. Levin[108g] emphasized the fact that in asthma caused or complicated by bacterial infection Benadryl was practically without effect. In cases of migraine the observations[113] have been more limited and there are not sufficient data as yet to allow any conclusions to be drawn. While in certain instances some relief may have been obtained, in others the headaches were definitely aggravated.

Administration and Reactions.—Benadryl is usually administered orally in 50 mg. capsules. In acute conditions individual doses of 50 mg. may be taken, while for persistent symptoms doses of 50 mg. four times a day may be used. Larger doses are not tolerated well by the majority of persons. In infants 10 to 20 mg. doses have been employed, and in children up to 8 or 10 years 25 mg. doses were used. Logan[108d] has found the effective dose in infants around 2 mg. per pound (454 Gm.) of body weight. The drug has also been used parenterally. I have noted that intramuscular injections of 10 mg. were apt to produce more intense action than did oral doses of 50 mg. McElin and Horton[108b] frequently employed intravenous injections.

The most common side reactions from Benadryl are drowsiness, lassitude and dizziness. These reactions are undoubtedly closely related and may be regarded as the result of a depression of the higher centers. To some degree these symptoms are present in more than 50 per cent of persons. In many they are of a minor degree and in others this effect is lessened or lost in one or two days. Many patients, however, have sufficient sleepiness to interfere seriously with their ordinary activities, and the drug has to be discontinued. Other side effects have been dryness of the mouth and nose, hot flushes, nausea, insomnia and aggravation of an existing headache or asthma.[113]

PYRIBENZAMINE (N′PYRIDIL-N′BENZYL-N-DIMETHYLETHYLENEDIAMINE)

This compound has the structural formula:



It will be observed that pyribenzamine differs from Antergan only in the substitution of the pyridil for the phenyl ring, and from Neoantergan by the omission of the methoxy group. These slight alterations, nevertheless, suffice to modify the action of these drugs.

Pyribenzamine was found by Mayer and his associates[114] to be the most promising of a series of histamine antagonists which they studied. In experiments on asthma and convulsions produced in guinea pigs by the inhalation of histamine, it was found that the subcutaneous injection of 0.1 mg. per kilogram of body weight of pyribenzamine was as effective a preventive as 1.0 mg. per kilogram of body weight of Antergan. According to Mayer,[115] subcutaneous injection of 5 mg. per kilogram of body weight of Pyribenzamine protected against sixty to one hundred and twenty lethal doses of histamine given intravenously. In comparison with the protective effect of similar amounts of other antagonists, the figures obtained were as follows: 929 F, three lethal doses; 1571 F, four to six lethal doses; 2325 RP, eight to ten lethal doses, and 2339 RP (Antergan), forty lethal doses.

Mayer[115] also reported that a concentration of 0.02 microgram per cubic centimeter of Pyribenzamine was capable of preventing the contraction of the guinea pig intestine from histamine diphosphate in concentrations up to 1.0 microgram per cubic centimeter. Its anti-acetylcholine action was of a much lower order. Although Pyribenzamine has a definite oxytocic action its antihistaminic activity is much higher, and as a result it can be shown that 10 to 50 micrograms per cubic centimeter of Pyribenzamine prevents the histamine contraction of the guinea pig uterus. Mayer has stated further that Pyribenzamine in subcutaneous doses of 0.1 mg. per kilogram of body weight will protect guinea pigs against anaphylactic death.

It has been shown by Yonkman and his associates[116] that in the dog a dose of 3.5 mg. of Pyribenzamine per kilogram of body weight is sufficient to protect against anaphylaxis. The maximum tolerated doses of the drug, according to Yonkman,[117] are 20 mg. or more per kilogram of body weight in the guinea pig. Toxic doses produced excitation up to the point of convulsive seizure. Concentrated solutions administered hypodermically produced local necrosis of tissue. As a further pharmacologic action of Pyribenzamine, it was shown that it had an inhibiting action on histamine salivation in cats[118] and that it prevented histamine whealing in rabbits.[119]

Whealing Phenomena.—In experiments on whealing in man Friedlaender and I[120] have found that Pyribenzamine has an action similar to, and probably more potent than, that of Benadryl. This inhibiting action on whealing was best noted when a solution of the drug applied locally was effective in inhibiting the whealing phenomena of histamine, specific antigen reactions, the specific reactions in passively sensitized sites, codeine, atropine, physostigmine, pilocarpine and bee venom.

Urticarial Dermatoses.—Arbesman and his associates[121] were the first to conduct therapeutic trials with Pyribenzamine. In acute urticaria they obtained relief in 93 per cent of patients, while in chronic urticaria 75 per cent were benefited. In a series of 37 patients with urticaria and angioneurotic edema whom we[122] treated with Pyribenzamine 29, or 78 per cent, obtained satisfactory relief. The majority of our cases were of the chronic type and we saw no particular difference between the response of the acute and chronic forms of urticaria. In some instances of angioneurotic edema, particularly those with huge swellings, larger doses (100 mg.) of the drug were required. In some instances the lesions were not as well controlled as the itching. In 6 cases of the serum sickness type caused by penicillin and in 2 caused by sulfonamide compounds, relief from itching and swelling was obtained, but the arthralgia was less responsive to this medicament. Results were also obtained in urticarial dermatoses caused by barbiturate compounds. Pyribenzamine was also effective in the relief of dermographism or urticaria factitia.

Dermatitis.—Pyribenzamine was found by us to be effective in the relief of itching in acute and chronic atopic dermatitis in 16 of 20 patients: the relief of the itching and the resulting scratching frequently was responsible in producing improvement in the cutaneous lesions. However, curative action was not noted. Pruritus vulvae and pruritus ani were also controlled symptomatically. Contact dermatitis was less responsive to the drug.

Hay Fever and Vasomotor Rhinitis.—According to Arbesman and his co-workers[121] the drug produced improvement in 85 per cent of patients with seasonal hay fever and 58 per cent of vasomotor rhinitis. In our[122] group of 254 hay fever patients 210, or 82 per cent, showed benefit, while in 130 patients with vasomotor rhinitis 64 per cent were benefited. The sneezing and rhinorrhea as well as the nasal blocking were relieved. Relief with Pyribenzamine was more noticeable in those who had had desensitizing treatment. Many of the patients listed as relieved were not helped by the drug when the symptoms became more severe. Since the 1946 ragweed season was unusually mild, it is not unlikely that in more severe hay fever seasons relief obtained by use of these drugs would be less. The persistent blockage of the nose experienced by some patients at any time of the season and by others toward the end of the season was influenced little by the use of these drugs. In 2 patients with decided nasal blocking due to the rebound action from nasal vasoconstrictors, the first dose of Pyribenzamine produced dramatic relief. The patients with seasonal hay fever included those who were sensitive to grass pollen, oak pollen, fungi and ragweed. Relief was usually noted in one-half to one hour following the first dose, although in some instances benefit was apparent only after two or three doses of the drug had been taken. It was noted by Arbesman's group of investigators as well as by my associates and myself that Pyribenzamine combined with ephedrine or aminophylline frequently was more effective than any one drug alone.

Asthma.—Benefit in asthma was noted by Arbesman and his associates[121] in 46 per cent of their seasonal cases and 37 per cent of the chronic type. In our series of 121 patients with asthma or allergic bronchial cough, 34 (or 28 per cent) were definitely benefited. The practically complete and rapid relief of the asthmatic attack obtainable from the use of epinephrine hypodermically was not noted with that of Pyribenzamine orally. Where relief was present it was usually only moderate. Spasmodic allergic cough was benefited more than dyspnea. It is well to remember that the asthma accompanying hay fever was seldom prevented by the use of the drug.

Miscellaneous Conditions.—In some instances of migraine, Pyribenzamine produced some relief, but its action in these cases was by no means consistent. In acute gastrointestinal upsets from food allergy, there was indication of benefit. We have observed also that in patients undergoing specific desensitization therapy the tendency to repeated constitutional reactions evident in a select few could, for the most part, be prevented by the administration of a dose of the drug prior to the specific treatment. This, however, does not mean that the patient is relieved from all symptoms of reaction or that he is secure from reactions due to large increments of antigen. Arbesman and his associates have also noted the ability of Pyribenzamine to prevent constitutional reactions.

Side Reactions.—Reactions other than the therapeutic effects desired are fairly common, but on the whole they are neither severe nor serious. The presence or absence of reactions was recorded in 598 patients. Out of this number 127 (or 23 per cent) admitted or complained of side reactions. Drowsiness and lassitude were observed in 18 per cent; dizziness in 13 per cent; nervousness or insomnia in 10 per cent; dryness of the mouth, throat or nose in 8 per cent and palpitation in 5 per cent. Other occasional side reactions were headache, burning on urination, gastric irritation, hypotension, diarrhea and tightness in the chest. The side effects in the vast majority of instances were moderate. In a few they were sufficiently intense, however, to prevent the patient from continuing the use of the drug.

Pyribenzamine was usually administered orally in 50 mg. doses three or four times a day. In some instances 100 mg. doses were effective when the smaller doses failed. In other instances 25 mg. doses were sufficiently effective. Children tolerated proportionately higher amounts than would be expected, most of them taking 25 to 50 mg. doses. The medicament was given in tablet form, preferably not on an empty stomach. In many instances where the allergic manifestation was not continuous, individual doses were taken as needed.

COMPARATIVE STUDIES

A comparative experimental and clinical study of the histamine antagonists currently proposed for clinical use was needed. We felt that these observations made on all the drugs by the same experimenters and by the same technics and standards should give valuable data. The drugs subjected to these studies were: Antergan, Neoantergan, Benadryl and Pyribenzamine.

Whealing from urticariogenic agents on the human skin was inhibited by all antagonists, but apparently Pyribenzamine and Neoantergan were the most potent in that respect.[105] Experiments were performed [123] on the effect of a standard dose (3 mg. per kilogram of body weight) of the drug in the prevention of death from histamine injected intravenously in the guinea pig. As compared with 0.4 mg. of histamine base per kilogram of body weight which was fatal to all unprotected animals, the following amounts of histamine were required to produce fatal reactions in all animals under the influence of the histamine antagonists (3 mg. per kilogram): Benadryl, 2.0 mg.; Antergan, 2.4 mg.; Pyribenzamine, 15.0 mg.; and Neoantergan, 50.0 mg. In numerous experiments with injections of histamine there was no indication that these injections conferred any degree of histamine tolerance to the animals.

Experiments on the protective effect of the various drugs in anaphylactic shock [124] have not indicated comparable differences in activity such as were found in the case of antihistaminic action. However, this phase of the work, together with studies being made on antianaphylactic and antihistaminic activity of the drugs in vitro and studies being made on toxicity will be reported at a later time.

In our therapeutic trials we employed chiefly Benadryl and Pyribenzamine. In the urticarial dermatoses, in atopic dermatitis and in the serum sickness type of reactions from penicillin and sulfonamide drugs, Benadryl and Pyribenzamine were fairly equal in their effectiveness. Occasionally one or the other was more effective. When Benadryl produced better results it was almost always in those instances where the additional sedative effect of the drug was an advantage. There were some patients who obtained inconsiderable results with Benadryl but had decided benefit from Pyribenzamine. In most of these the advantage was due mainly to the fact that larger doses of Pyribenzamine than of Benadryl could be tolerated.

The outstanding difference in clinical effectiveness between the two drugs occurred in the allergic manifestations of the respiratory tract. In perennial vasomotor rhinitis benadryl gave relief to 15 per cent of the patients, while Pyribenzamine [122] was of benefit to 64 per cent. In the seasonal hay fever series the advantage was also in favor of Pyribenzamine; 82 per cent of the patients were helped with Pyribenzamine and 52 per cent with Benadryl. In 52 patients with perennial or seasonal allergic rhinitis in whom both drugs were tried, comparisons could be made. Thirteen were helped by both. In 24 relief was obtained by the use of Pyribenzamine without any appreciable effect from Benadryl, while in 6 the Benadryl was more effective. In asthma or allergic cough Benadryl gave some measure of relief in 10 per cent, while Pyribenzamine helped 28 per cent. In 34 patients in whom a clinical comparison of both drugs was made, 23 did not obtain relief from either drug, while 4 were helped by both. In 7 who were not benefited by Benadryl, Pyribenzamine gave some relief. There was not one case that was pyribenzamine-resistant in which relief was obtained by the use of Benadryl. It should be emphasized again that with either drug the relief was not of the order usually obtained with ephedrine or epinephrine. However, in some patients who failed to respond or responded only partially to the sympathomimetic drugs, Benadryl and Pyribenzamine were of some aid.

In 44 patients with respiratory allergy, chiefly ragweed hay fever, comparison was made between the effectiveness of Pyribenzamine and Neoantergan. In 9 no response was obtained from either drug. In 11 both drugs were equally effective. In 17 the results were in favor of Pyribenzamine, while in 7 Neoantergan was favored. Doses of 100 to 200 mg. of Neoantergan were required for therapeutic effect, but toxic reactions were less frequent with this drug.

A comparison of the side effects of these two drugs gives the following impressions. More than half of the patients taking 50 mg. doses of Benadryl complain of untoward effects, among which sleepiness is the outstanding reaction. In a good many instances this complaint of lassitude or dizziness is of such magnitude as to make it impractical to continue the therapy. The side reactions from Pyribenzamine occur in less than 25 per cent of the patients and are of a milder order than those from Benadryl. Slight drowsiness is about the most commonly observed effect, but it is infrequently of the degree obtained with Benadryl. It is interesting to note that those patients who observed a sedative effect from the use of Pyribenzamine found that this effect was invariably more pronounced when Benadryl was administered. In only a relatively few was the use of Pyribenzamine contraindicated because of its side reactions. One of the greatest advantages of this drug over Benadryl is that the toleration of larger doses of Pyribenzamine (100 to 150 mg.) enables one to obtain results in some cases where the smaller doses of Benadryl (50 mg.) are not effective.

COMMENT

The general subject of the antihistaminic drugs is reviewed in several articles.[125] A new era in the field of antihistaminic and antiallergic actions is rapidly developing. There are now available drugs which experimentally can be shown to have antihistaminic and antianaphylactic efficiency and a fair degree of palliative usefulness against allergic manifestations. It should be distinctly understood that these drugs do not immunize the patient or protect him from the effects of the allergic reaction for any extensive period. To the best of our knowledge these drugs operate by competing with the liberated histamine in their attachment to the receptor cell. Therefore, the benefit is only symptomatic and lasts only for a few hours from each dose of the medicament.[126] It is important for the allergic person to continue with his allergic management and with his specific desensitizing program where indicated. It is likely that the employment of desensitization combined with the use of histamine antagonists during the stage of active allergic symptoms may be better than the use of either treatment regimen alone.

Although the preliminary experimental observations of others would indicate that the antagonists of histamine do not interfere with the antigen-antibody reaction or with desensitization, this question has not been conclusively settled. It is important to keep in mind that further investigation may possibly show that while the patient is being helped temporarily by one of these drugs the long term program of creating immunity may be interfered with by the same drug. The immediate side reactions from these drugs may be a handicap in their use. The remote toxic effects have not yet been sufficiently studied. In the past, the toxic reactions of new drugs in many instances have not been apparent for a considerable period after their widespread use.

The currently available histamine antagonists are not ideal. They do not work in all types of allergic manifestations, nor are they of help in all cases of any particular syndrome. The side reactions limit the size of the doses. It is likely that within the near future more potent and less toxic histamine antagonists will emerge and be able to overcome some of these difficulties. On the other hand, it must be admitted that since it is not definitely known that histamine release is the only injurious effect of the allergic reactions, even the most potent antagonists of histamine may fail to be completely effective in the relief of allergic manifestations. There is also the possibility that other means will be found to combat the problem of allergy, among which is the inhibition of the antigen-antibody reaction or the prevention of the release of toxic substances in such reactions.

In this connection it is well to realize that allergic manifestations are prone to cyclic changes and periodicities, varying from hour to hour, day to day, week to week and season to season. For this and other reasons misinterpretation is frequent in the evaluation of the efficacy of remedies in allergy. The following criteria are suggested to test the effectiveness of a symptomatic remedy in allergic disease:

1. Unquestioned relief of symptoms must be obtained on the administration of the drug on repeated occasions.
2. Recurrence of symptoms should follow the discontinuance of the medicament.
3. The relief should be obtained under sufficiently controlled conditions and under varying circumstances so that it cannot be attributed to normal fluctuations in tolerance or to external factors, such as weather or pollen concentration. (The 1946 ragweed season was unusually mild.)
4. Whenever possible (urticaria, hay fever and asthma) objective changes should confirm subjective claims.
5. Placebo medication should fail to produce relief.

SUMMARY

The recognition of the role of histamine in the mechanism of anaphylaxis and its probable role in allergy has led to various attempts to diminish the action of this poison. That an increase in tolerance to histamine cannot be expected from injections of histamine is supported by the preponderance of experimental evidence in animals and man. The enzyme histaminase lacks an inhibiting or neutralizing effect on histamine in the living animal and does not exert a specific action on anaphylaxis or allergy. The evidence for an increased tolerance to histamine and for a resulting specific antiallergic action from the injection of histamine-azoprotein is doubtful.

In the last few years histamine antagonists of various types have been tried in histamine shock, anaphylaxis and allergy. The amino acids, histidine, cysteine and arginine, were found too weak in their action and too toxic. The early French synthetic compounds proved fairly active in histamine and anaphylactic reactions but were too toxic for clinical use.

The more recent antagonists of histamine are chemically related and have some degree of clinical usefulness. These are the French compounds Antergan (N′phenyl-N′benzyl-N-dimethylethylenediamine) and Neoantergan (N-p-methoxybenzyl-N-dimethylaminoethyl *a* aminopyridine) and the American compounds Benadryl (B-dimethylamino ethyl benzhydryl ether) and Pyribenzamine (N′pyridil-N′benzyl-N-dimethylethylenediamine). Benadryl and Pyribenzamine are useful symptomatic remedies in the treatment of the urticarial dermatoses, atopic dermatitis (flexural and infantile atopic eczema), reactions to penicillin and sulfonamide, some other types of dermatitis and seasonal hay fever. In the latter syndrome the order of effectiveness of the antihistaminic drugs is: Pyribenzamine, Neoantergan and Benadryl.

The usefulness of Benadryl and Pyribenzamine against perennial vasomotor rhinitis and asthma is more limited. The evidence thus far indicates that Pyribenzamine is the more effective of the two drugs against these manifestations.

Both drugs give a high incidence of side reactions, among which sedation and drowsiness are most commonly observed. These reactions are more frequent and of greater intensity in the case of Benadryl.

The use of these histamine antagonists should be tempered with the following considerations: A cure or lasting improvement is not to be anticipated as a result of the action of these drugs; at best they exert only a temporary palliative action in allergic conditions. Many manifestations and many patients will fail to respond to them, and others will be helped by the employment of additional palliative measures. The specific allergic methods (elimination and desensitization) should not be abandoned, as at present they constitute the sole means of achieving lasting results. In addition to precautions against immediate toxic reactions, it should be remembered that the remote toxicity from these drugs has not been sufficiently ascertained up to this time.

THE BRUTALITIES OF NAZI PHYSICIANS

On December 5 a new series of Nürnberg trials will begin, this time involving twenty-three Nazi physicians who are charged with the crime of having conducted experiments on human beings resulting in innumerable deaths. A few months ago at the request of the federal government the Board of Trustees of the American Medical Association delegated Dr. A. C. Ivy, vice president of the University of Illinois, to represent the Association in an investigation of these acts of inhumanity, as a member of a group that will present evidence at the trials. On his return to the United States Dr. Ivy made his report to the government and at the same time directed a copy to the Board of Trustees. The report was referred by the Board of Trustees to the Judicial Council of the Association, with a request that it be presented to the meeting of the House of Delegates to be held in Chicago December 9-11. Thus there will become available an official statement from the House of Delegates regarding its attitude toward the acts committed by these German physicians.

Since the earliest times society has expected of the physician a standard of conduct compatible with the nature of his profession. "The Principles of Medical Ethics" say "A physician should be 'an upright man, instructed in the art of healing.' Consequently, he must keep himself pure in character and conform to a high standard of morals, . . ."

The report of the Mission to the European Theater Concerning War Crimes of a Medical Nature showed that certain German physicians and scientists were involved in the perpetration of both nonexperimental and experimental crimes and barbarities. The nonexperimental crimes included mass killings of persons who were about to die from disease, malnutrition and old age. Poor workers were placed on a hunger diet and when they became weakened from malnutrition were killed. Mass killings were practiced to make more room in overcrowded concentration camps and prisons. Hundreds of thousands of gypsies, Poles and Russians were killed by exposure to the fumes of potassium cyanide and the intravenous injection of cresol, chloral, veronal, morphine and scopolamine as a part of the technic for exterminating other people in order to make more room for Germans. One series of murders was done to provide skeletons for an anthropological museum. Operations were done on human beings as part of the procedure in training students in surgical technics. The selection of persons to be killed was done by physicians, and the killing was done under their supervision.

These brutalities were supplemented by a series of experiments on human beings such as have never before occurred in the history of the world. Medical science has been advanced in our own country and in some other countries by experiments on human beings who volunteered for the purpose. Conspicuous were the volunteers in the transmission of yellow fever in Cuba, the prisoners in Mississippi who volunteered for experiments in pellagra and those in Colorado who volunteered for experiments with tuberculosis. During the war just ended great numbers of our soldiers volunteered for experiments with malaria, influenza and other infectious diseases. In every instance the right of the human being to determine for himself whether or not he would participate was recognized. In the American army the tradition is well established that human beings, even under military conditions, are not ordered to submit to procedures that violate the sanctity of their own persons. The medical profession of our country in accordance with its traditions would support any medical officer who would refuse to obey an order from a line officer which would violate the sanctity of any human being, if any line officer should give such an order. Neither would the American tradition require a physician to debase himself or his profession by participating in such a performance even at the behest of the highest political leaders.

The records clearly establish that certain Nazi physicians performed experiments on human subjects without their consent and with complete disregard for their human rights. These experiments were often conducted with unnecessary suffering and injury, and death was a certain outcome. Some of the experiments were sadistic and were performed by pseudoscientists and untrained personnel without adequate reason. Apparently seventy physicians and scientists were involved, although there may have been many more. Three well known scientists have been indicted, the most prominent being Dr. Sigmund Schilling, whose name has been associated with study on the blood.

The report to the Secretary of War by Dr. Ivy lists the following experiments:

1. The injection of virulent typhus into a nonimmunized control group of human subjects.

2. The introduction of living tuberculosis germs into the trachea.

3. The study of remedies for phosphorus burns of the skin.

4. The excision of the ligaments of muscles about the joint to ascertain the extent of functional impairment.

5. The shortening of a limb by the excision of a section of bone to ascertain how much bone may be removed without impairment of function.

6. The incomplete removal of a longitudinal section of bone to ascertain how much weight the remnant will support.

7. The transplantation of tissues of various types. Attempts were made to transplant legs and other organs which animal experimentation has shown to be impracticable. In one instance a piece of "hair-growing skin" was transplanted to the nose of a Jewess.

8. In several different experiments virulent germs, including the "gas gangrene" producing bacillus, were injected into the leg muscles, and various types of chemotherapeutic and surgical treatments were employed at different stages of the infection to ascertain the best treatment. In one experiment pieces of leg muscle were rendered ischemic and traumatized to render the "gas bacillus" more virulent.

9. A study was made to ascertain how best to rewarm a subject whose body temperature was reduced to a low level (75 to 80 F.) by exposure to "wet cold" (cold water) and "dry cold" (cold atmosphere). Frostbite also was produced in another series of experiments.

10. Some experiments were done in which rupture of the uterus was produced.

11. Experiments on artificial insemination with subsequent artificial abortion were performed.

12. An attempt was made to produce multiple ovulation and conception with the idea of increasing the rate of reproduction of the herrenvolk. Indecencies characterized these experiments.

13. Studies were made to ascertain how a population could be sterilized without their knowledge, so that the sterilization could be accomplished without the fact becoming available for propaganda by the enemies of the reich. Castration by ordinary methods was too open. One method under study was to place the dried juice of a plant in the food of the population. Another method under study was to expose men and women to a castration dose of x-rays while they were filling out governmental forms. A third method consisted in injecting the cavity of the uterus with a sterilizing agent during the course of a routine physical examination of the women of the population. Even the number of women that could be sterilized in one day by one assistant was estimated.

14. The pathologic changes caused by and the lethality of "war gases" were apparently studied.

15. Experiments on explosive decompression were performed. The subjects were suddenly exposed to an altitude of 40,000 feet in an altitude chamber and kept there for twenty or thirty minutes without oxygen. This, of course, killed the subjects, and then autopsies were performed at altitude to search for gas bubbles in the blood vessels and tissues.

16. The lethal effects of poisoned bullets were studied to ascertain particularly the time of onset of symptoms of poisoning and how long the person wounded by the poisoned bullet would live.

THE JOURNAL has commented previously on the experiments with frozen men in which nude young women were forced to lie next to them in an attempt to encourage recovery. The foreign correspondents of THE JOURNAL have reported investigations made by leaders of medicine in other countries which substantiate fully the list of experiments described in the Ivy report.

Obviously, all of these experiments involving brutality, torture and murder were done without any basis in any laws either of Germany or of the Hague Convention. Certainly such experiments are contrary to the laws of humanity and the ethical practices of the medical profession which have prevailed for more than twenty centuries. These experiments were done without the consent of the human beings who were the subjects; they were done frequently without any adequate scientific reason; they were done often by people not qualified, and they were done in many instances with certain knowledge that the experiments might lead to permanent disability or death. Not the slightest good has resulted to mankind from these experiments. The basic sciences and medicine languished in Germany during the period of the war more than in any other country.

Perhaps most serious of all is the failure of German medical organizations and societies to express in any manner their disapproval of these widely known experiments. Physicians have a right to expect that men trained in the traditions of medicine would refuse to participate in any way in such acts of inhumanity and brutality. In some instances the defense has been offered that these experiments were conducted under the highest authority of the German state. That cannot possibly be considered in the slightest an extenuation of the failure of these physicians to act in accordance with the principles and traditions of their profession. Robert Burns wrote many years ago "Man's inhumanity to man makes countless thousands mourn." The inhumanity of these German physicians has stirred horror and disgust among physicians of every other nation of the world. From no other medical profession has there come evidence of anything resembling these sadistic procedures perpetrated in the name of science and camouflaged by a mask of research.

POLIOMYELITIS PORT OF ENTRY

Thirty-five years have passed since Flexner,[1] after initial animal experiments, suggested that the nasal mucosa, or, more correctly, the olfactory cells and nares, constitute the normal gateway through which poliomyelitis virus gains access to the central nervous system of man. Doubt gradually developed, following failure of local applications of alum or picric acid [2] to reduce the incidence of poliomyelitis in several outbreaks. Various potential pathways of infection other than the olfactory nerves were subsequently suggested, such as entrance through the taste buds [3] or other terminals of the ninth and tenth nerves,[4] through the abdominal sympathetics [5] or through the intrinsic ganglions of the intestine, with centripetal spread through the vagus.[6]

At present agreement is almost unanimous by those who have investigated human material that the olfactory nerve system is rarely involved. Kessel and his associates,[7] for example, found virus in only one olfactory bulb out of 11 fatal cases studied. There is, however, no unanimity of opinion as to which of the other suggested ports of entry play a dominant part. Statistical evidence toward a solution of this problem has been recently reported by Faber and his associates [8] of the Department of Pediatrics, Stanford University School of Medicine.

The San Francisco pediatricians made detailed microscopic studies of lesions in the nervous system in a series of 8 fatal cases occurring during 1943 and 1944 in the San Francisco Bay area. The cases were typical, and the diagnosis was confirmed in all but 1 instance by transmission of the disease to rhesus monkeys. All the patients died between the third and the ninth day from the effects of the disease, excepting 1 patient, who died on the twenty-fifth day from perforation of the esophagus.

Faber concludes that there appears to be no single port of entry in human poliomyelitis. Almost any nerve system with peripheral endings in the mucous surfaces can, if exposed, convey the virus in a central direction to its regional ganglions and thence, if the process continues, into the central nervous system. Their limited statistical evidence suggests the following relative frequencies of primary infection: (*a*) trigeminal afferent system (fifth cranial) very frequent, (*b*) visceral afferent system (ninth and tenth cranial) fairly common but less than the fifth, (*c*) gustatory system (seventh, ninth and tenth cranial) occasional, (*d*) sympathetic systems, upper levels (pharynx, bronchial tree, upper esophagus) occasional, (*e*) sympathetic system, lower (intestine) doubtful and (*f*) vagal efferent (parasympathetic) system (ninth cranial) and olfactory (first cranial) system uninvolved.

The pharynx thus appears to be an especially favorable site for the primary penetration of poliomyelitis virus into the body. Clinically there is apparently no constant correlation between the site (or level) of the initial penetration and the site or severity of the initial paralysis.

DIET AND MAN'S TOLERANCE TO COLD

The possibility that human tolerance to cold may be affected by diet, particularly by the water soluble vitamins, has been a matter of conjecture for many years. Recently a comprehensive study of the question has been reported [1] by a group of investigators at the University of Illinois. Twelve healthy young men were used as subjects. Experiments were conducted for a period of one hundred and fifty days to determine the effect of supplements of the water soluble vitamins to a basal diet containing only borderline amounts of ascorbic acid, thiamine, riboflavin and niacin on the ability of the subjects to withstand repeated exposure to cold. The exposure was of eight hours' duration either to intense cold (— 20 F.) with considerable protective clothing or to a cool environment (60 F.) with little protective clothing. The tolerance to cold was measured by changes in rectal and mean skin temperature and in the performance of a series of psychomotor, perceptual and intellective tests. The supplementary vitamins were alternated with placebos indistinguishable from the vitamin capsules.

After eighty-nine days the subjects fed only the basal diet did not show evidence that the diet was inadequate for normal nutrition excepting that the plasma ascorbic acid level decreased to a low value (0.2 mg. per hundred cubic centimeters) and the excretion of thiamine in the urine was reduced to a level indicative of borderline thiamine deficiency. A systematic study of the data secured from psychomotor, perceptual and intellective tests failed to reveal any consistent evidence that the vitamin levels of the basal diet were inadequate. Nor was there any discernible effect on the tolerance to cold as measured by changes in rectal and mean skin temperature, the latter varying with environmental temperatures, as has been recently emphasized.[2] The addition of the water soluble vitamins was likewise without effect on the tolerance to cold as well as on the psychomotor, perceptual and intellective tests.

---

[1] Glickman, N.; Keeton, R. W.; Mitchell, H. H., and Fahnestock, M. K.: Am. J. Physiol. **146**: 538 (July) 1946.

[2] Adolph, E. F., and Molnar, G. W.: Am. J. Physiol. **146**: 507 (July) 1946.

These careful studies thus indicate clearly that the ability of man to withstand the damaging effects of repeated exposures to cold cannot be appreciably altered by giving excessive doses of ascorbic acid, thiamine, riboflavin and nicotinic acid above the amounts required for apparently normal nutrition. The possibility that the water soluble vitamins might show a favorable effect in subjects with definite avitaminosis, of course, is not answered by these experiments.

Current Comment

THE QUESTIONNAIRE ON MILITARY MEDICAL SERVICE

Pursuant to a resolution passed by the House of Delegates of the American Medical Association in December 1945, the Board of Trustees appointed a Committee on National Emergency Medical Service to undertake a critical study of the duties of medical officers during the war, with special reference to (1) opportunities for study, research and actual treatment of the sick, (2) rotation of medical assignments and (3) quasimedical duties for which technicians and specially trained enlisted personnel might replace physicians. The committee is headed by Dr. Edward L. Bortz, Philadelphia, and includes Drs. Harold S. Diehl, Minneapolis; Perrin H. Long, Baltimore; Harold C. Lueth, Omaha; O. O. Miller, Louisville, Ky.; James C. Sargent, Milwaukee, and V. C. Tisdal, Elk City, Okla., thus having in its membership men who served in the Army and Navy medical departments and civilian physicians. Several months ago the committee sent a pilot questionnaire to 1,000 former medical officers and received 470 replies, which are an indication of the great interest in this study (see Organization Section, this issue, page 719). Now the committee is distributing the questionnaire to 45,000 medical officers who have been discharged from the armed forces. The questionnaire gives opportunity for an expression by the discharged medical officer of his observations and his opinions. The Bureau of Medical Economic Research of the American Medical Association has aided in the development of the questionnaire, so that the replies can be recorded on punch cards and permit statistical data which should be of vast help to the government services concerned as well as to the physician who volunteers his services in response to the nation's call. The preparation and the circulation of this questionnaire and the counting of the replies are a difficult, costly procedure. Physicians who receive the questionnaire can cooperate best by giving careful consideration to every question and answering as promptly and completely as possible.

U. S. MILITARY MEDICINE IN WORLD WAR II

The mortality rate from wounds among the combatant forces of the United States Army in World War II was less than 3 per cent, or well under one half of that in World War I, said to be variously from 7 to 10 per cent. These truly remarkable results are usually attributed to recent scientific advances, such as the antibiotics ("miracle drugs"), blood banks, blood transfusions and blood substitutes, such as plasma or serum albumin, and the use of new narcotics and anesthetics. The credit should actually be given to factors which made these discoveries and their application possible, namely the gradual growth of medical knowledge and expertness, largely unnoticed and unheralded. What is little appreciated is that the medical progress accomplished by American medicine in the interim between the two world wars is to a great extent due to standardization of medical schools by the American Medical Association and the standardization of hospitals by the American Medical Association and the American College of Surgeons, resulting in the highest type of training for medical students and interns. Waltman Walters [1] emphasizes that there were relatively few men of preeminent ability in surgery and its specialties in the former war, whereas there were at the beginning of this war literally thousands of well trained, capable surgeons in this country, many of whom were already members of the reserve corps of the Army and Navy. Graduate medical training has also been stimulated by the creation of specialty boards. The sulfonamides and penicillin were important factors in combating infection, while blood and plasma transfusions did much to counteract shock. Of the greatest importance, however, was the organization of the medical service which made it possible to treat most wounded men within a few hours from the time their injuries were received.

CONSERVATION OF HEARING

A long range program on the conservation of hearing has been projected by a special committee of the American Academy of Ophthalmology and Otolaryngology. In addition to research on specific otologic diseases, the objectives include the testing of the hearing of school children and the establishment of state programs to encourage legislation promoting such tests. Expansion of testing programs of adults is also recommended. An important part of the program involves the promotion of education regarding the problems facing those who are hard of hearing. The establishment of hearing rehabilitation clinics in cooperation with medical schools, hospitals and already existing clinics is to be promoted. The medical profession at large can agree with the objectives defined, and its cooperation is certain.

Washington Letter

(From a Special Correspondent)

Nov. 18, 1946.

Taft Plans to Reintroduce Bill to Provide Medical Care for the Poor

Senator Robert Taft of Ohio plans to reintroduce for consideration by the incoming Republican Congress bills he authorized to spend millions of dollars in federal funds for social welfare. The measures would give federal money to states for medical care for the poor, provide federal aid for education and finance the controversial Wagner-Ellender-Taft housing bill. The medical care bill would allot $200 million a year to the states for use in providing general medical care for the poor. To get the federal money, the states would have to set up a system by which medical care would be made available to every resident unable to pay for its cost. The federal aid for education bill would seek to insure that every school district in the United States has $40 a year to spend on the education of each child of school age. Some districts have as little as $7 a year per child, and others have as much as $150.

Crabtree Describes U. S. P. H. S. Construction Plans

Speaking for Surg. Gen. Thomas Parran, who could not attend the dedication ceremonies of the new infectious disease laboratory of the U. S. Public Health Service because of illness in his family, Dr. James A. Crabtree, deputy surgeon general, described the laboratory's great growth in ten years from small beginnings. He told of construction plans, estimated to cost between $15,000,000 and $20,000,000, for expansion of the National Cancer Institute, for actual treatment of cancer for an institute for research in mental diseases and for a national dental institute. It is planned to use at present the industrial hygiene department for joint study of radioactive isotopes in medicine and other fields with the Bureau of Standards. Dr. R. E. Dyer, director of the National Institute of Health, of which the new laboratory will be a unit, traced the sixty years of U. S. P. H. S. research. Dr. Detlev Bronk, chairman of the National Research Council, emphasized the need for government sponsored research to pioneer in new fields.

Amputee Is First Disabled Man to Be Enlisted by Army

Under a policy announced by General Eisenhower, chief of staff, an army sergeant who lost his left arm in aerial combat over Rangoon in 1944 has been the first man accepted in the program whereby 5,000 disabled veterans will be permitted to rejoin the service. The plan provides for veterans disabled in combat who meet the minimum physical standards for enlistment (with the exception of the specific disability) and who will require no more hospitalization.

Health Official Denies that Old Newspapers Carry Disease

Dr. Hobart M. Corning, superintendent of District of Columbia schools, was advised by George Ruhland, health officer, that there is no basis for the assertion of school custodial forces that handling old newspapers by children in salvage drives exposed them to contagion. Dr. Ruhland said that the common communicable diseases are rarely if ever spread by newspapers, and then only under most unusual circumstances. He said that bank tellers are not more frequently affected by diseases, although they are constantly handling paper money.

President Gives Final Approval for Nevius Tract as Veterans Hospital

Controversy over whether the Nevius tract, adjoining Arlington National Cemetery, should be used as the site of a 750 bed veterans hospital for the Washington area has ended. President Truman has signed the bill authorizing its use. Veterans administrator Omar N. Bradley and Dr. Paul R. Hawley, medical director, said that the hospital might be completed by the middle of 1948.

Coming Medical Meetings

American Medical Association House of Delegates Supplemental Session, Chicago, Dec. 9-11. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Conference of State Secretaries and Editors, Chicago, Dec. 7-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Allergy, New York, Nov. 25-27. Dr. Karl D. Figley, 316 Michigan St., Toledo 2, Ohio, Secretary.

American Academy of Dermatology and Syphilology, Cleveland, Dec. 7-12. Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, N. Y., Secretary.

American College of Surgeons, Cleveland, Dec. 16-20. Dr. Dallas B. Phemister, 40 E. Erie St., Chicago 11, Secretary.

American Society of Anesthesiologists, New York, Dec. 12. Dr. Curtiss B. Hickcox, 745 Fifth Ave., Room 1503, New York, Secretary.

National Society for the Prevention of Blindness, New York, Nov. 25-27. Mrs. Eleanor Brown Merrill, 1790 Broadway, New York 19, Executive Director.

Post Graduate Medical Assembly of South Texas, Houston, Dec. 3-5. Dr. M. B. Stokes, 229 Medical Arts Bldg., Houston, Secretary.

Puerto Rico, Medical Association of, Santurce, Dec. 13-15. Dr. Rafael A. Vilar, P. O. Box 3866, Santurce, Secretary.

Radiological Society of North America, Chicago, Dec. 1-6. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse 2, N. Y., Secretary.

Southern Surgical Association, Hot Springs, Va., Dec. 10-12. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Western Surgical Association, Memphis, Tenn., Dec. 5-7. Dr. Warren H. Cole, 1853 W. Polk St., Chicago 12, Secretary.

COMMITTEE ON NATIONAL EMERGENCY MEDICAL SERVICE

Herewith is a greatly reduced facsimile of the front side of the postwar questionnaire prepared by the Committee on National Emergency Medical Service. This questionnaire has been sent to 45,000 physicians who have been discharged from the Army and Navy medical departments. The questionnaire provides opportunity to identify the physician by his qualifications and to indicate the number of years of service and the government agency with which he served. It will indicate the portion of the world in which the service was rendered and the type of unit with which the physician was associated. The controversial question as to the amount of time actually given [illegible] of his profession in the armed forces and the need for the number of physicians employed will be subjected to analysis based on the actual data. The questionnaire indicates also the kind of training received by the physician and its usefulness to him, his opinion of the nature and quality of the assignments that he received and the extent to which his professional skills were utilized. Finally, the questionnaire will indicate the extent to which he was given opportunity to keep abreast of medical advancement through various technics and his opinion as to the relative usefulness of these technics. Opportunity is given also for any physician to discuss in extenso some particular phase of his medical service if he wishes to do so.

GOVERNMENT SERVICES

ARMY

VACCINATION OF MILITARY PERSONNEL AGAINST INFLUENZA

During the fall and winter of 1946 and 1947 vaccination of military personnel against influenza will be undertaken on evidence of an incipient or beginning outbreak of the disease. The policies and procedures outlined will apply:

For Installations in Continental United States:

1. On receipt of this circular (312 W. D., Washington, Oct. 19, 1946), all camps, posts and stations will submit requisitions to the St. Louis depot for influenza virus vaccine (unit -30 cc. vial) medical catalogue number 1605900. The amount requisitioned will be calculated on the basis of thirty-eight vials per thousand troops as estimated for Dec. 1, 1946.

2. Shipment of the vaccine will be deferred until there is definite indication for vaccination and will be effected by the depot when directed by the Surgeon General. Vaccination of all military personnel will be accomplished at once on receipt of the vaccine. This method of distribution is directed because of the necessity for conserving materials and for maintaining a strategic central reserve of vaccine. Plans for orderly and expeditious vaccination of all military personnel, including ready availability of necessary equipment, will be made at all stations to insure the rapid completion of the program.

3. All suspected outbreaks of influenza occurring in a military installation or command will be immediately reported to the Surgeon General by telephone or telegraph.

4. Each army area laboratory is equipped for the performance of specific diagnostic tests for influenza A and B. On the ocurrence at any army installation of cases suspected of being influenza, acute and convalescent blood serum specimens (4-5 cc.) will be aseptically collected from each of several representative patients. From each patient selected the first or acute specimen should be obtained within forty-eight hours of the onset of illness and refrigerated. The second or convalescent specimen taken seven to ten days later should be paired with the first or acute specimen and both, properly labeled, forwarded together to the appropriate army area laboratory. These specimens need be obtained from only a limited sample (10 to 20 cases) of suspected cases early in an outbreak in order to establish the presence of influenza A or B. These tests are confirmatory only, and the report of suspected outbreaks as required in 3 should not await their outcome.

For Overseas Installations:

1. Influenza vaccine is to be requisitioned from the United States in accordance with the instructions published in War Department radios of Sept. 13, 1946. A plan should be devised to insure rapid and complete distribution of this material to all military installations should the need for vaccination arise. Each installation should be instructed to have ready the equipment necessary for the immediate and complete vaccination of all military personnel on receipt of instructions to vaccinate.

2. The decision to employ vaccination against influenza will rest with the oversea commander and will be determined by evidence of an incipient or beginning influenza outbreak. Oversea commanders will notify the Surgeon General by radio immediately when the decision to vaccinate is made and will state the indications therefor.

3. All available facilities should be utilized for the early detection and reporting of suspected outbreaks of influenza. Special radio reports should be made to the Surgeon General on the occurrence of suspected or proved outbreaks.

COMMENT

Influenza vaccination will consist of a single dose of 1 cc. of the vaccine, administered subcutaneously. Precautions will be taken to avoid administering influenza vaccine to persons sensitive to eggs. To elicit a history of egg allergy, all persons to be vaccinated should be asked if they are able to eat eggs. The vaccine should be withheld from those who answer in the negative unless further investigation rules out egg sensitivity. Record of vaccine administration should be made on WD AGO form 8-117 (Immunization Register); indication of egg sensitivity, if present, should also be entered on this form.

As indicated in the circular, influenza vaccination of army personnel during the coming season will be practiced not as a precautionary measure but as a specific control procedure to be applied if definite occasion arises. The value of influenza vaccine for the prevention of influenza A was well demonstrated in the series of controlled studies at a number of universities in 1943 and 1944 and reported in the *American Journal of Hygiene* in July 1945. It is felt that the value of vaccine for the prevention of influenza B has also been demonstrated, although quantitative data similar to that collected during the earlier trials are not available. The vaccine was used for all military personnel during the fall and winter of 1945-1946, the majority of troops having been vaccinated before the outbreak of influenza B which occurred last December. By comparison with civilian and other unvaccinated groups there can be little doubt that influenza B was present in army personnel to a considerably less extent than would have been the case had vaccination not been practiced. The observations of Francis in his article in The Journal, May 25, tend to corroborate this view.

ARMY AWARDS AND COMMENDATIONS

Brigadier General Ralph H. Goldthwaite

The Legion of Merit was recently awarded to Brig. Gen. Ralph H. Goldthwaite, M. C., U. S. Army, of Washington, D. C., "for outstanding services from August 1942 to October 1945 as commanding general, Army and Navy General Hospital, Hot Springs, Ark. He supervised the expansion of this installation and brought it to peak efficiency from the standpoint of patient care and hospital staff morale." The citation states that the great success which his efforts achieved was brought about by "superior professional ability and sympathetic understanding of the problems involved in operating this highly specialized medical center." Dr. Goldthwaite graduated from Harvard Medical School, Boston, and entered the service May 26, 1909.

Major Marcus Feinstein

The Army Commendation Ribbon was recently awarded to Major Marcus Feinstein, M. C., A. U. S., New York, whose skilful professional service rendered in connection with the care of patients and in the study of an outbreak of unusual acute respiratory disease in a bomber squadron returned from overseas contributed both to the welfare of the troops and to the early collection of essential medical data. The commendation stated that this combination of clinical and epidemiologic investigation constituted a valuable addition to knowledge. Dr. Feinstein graduated from New York Medical College, Flower and Fifth Avenue Hospitals and entered the service Nov. 14, 1942.

Colonel Earle Standlee

The Oak Leaf Cluster to the Legion of Merit was recently awarded to Col. Earle Standlee, M. C., U. S. Army, of Washington, D. C. The citation stated that "while serving as deputy surgeon, Mediterranean Theater of Operations, from June 1943 to July 1945, and chief surgeon, Mediterranean Theater of Operations, from July to October 1945, he displayed a fine sense of balance necessary between administrative and professional functions of the medical service and thoroughly and ably performed the coordination and implementation of medical policy throughout long and arduous campaigns." Dr. Standlee graduated from Baylor University College of Medicine, Galveston, Texas, and entered the service July 1, 1926.

Captain Howard J. Hartman

The Bronze Star was recently awarded to Capt. Howard J. Hartman of Waterloo, Iowa, the citation reading, in part, "for meritorious service in connection with military operations against the enemy at Toem, Dutch New Guinea, from Sept. 1 to Dec. 3, 1944. . . . While serving as ward officer in a clearing station for a task force he displayed a high standard of professional and military ability . . . his untiring efforts were an inspiration to the rest of the men in the hospital." Dr. Hartman graduated from Rush Medical School and entered the service Oct. 2, 1942.

Major Patrick M. Cmeyla

The Bronze Star Medal was recently awarded to Major Patrick M. Cmeyla, M. C., U. S. Army, of Sioux City, Iowa. The citation stated that "during eleven months' captivity in the Sendai Prisoner of War Camp No. 2, Taira, Japan, he did all within his power to alleviate the suffering of his fellow prisoners, and his performance under the most adverse conditions did much to maintain high morale among a large group of allied personnel." Dr. Cmeyla graduated from the University of Louisville School of Medicine and entered the service April 15, 1941.

Lieutenant Colonel Harold A. Abramson

The Legion of Merit was recently awarded to Lieut. Col. Harold A. Abramson, M. C., A. U. S., Cold Spring Harbor, L. I., N. Y., who as chief, physical chemical section, and assistant chief, defense material branch, Edgewood Arsenal, Maryland, from July 1942 to December 1943, carried out important research in the field of chemicals. "Displaying profound knowledge, a keen, creative mind and outstanding ability," says the citation, "he made vital contributions to the Chemical Warfare Service and thus to the war effort." Dr. Abramson graduated from Columbia University College of Physicians and Surgeons, New York, and entered the service July 11, 1942.

Captain John M. Bretz

The Bronze Star was recently awarded to Capt. John M. Bretz, M. C., A. U. S., of Huntingburg, Ind. The citation reads "For the superior service you have rendered as division medical inspector. Your inspections of the many and diverse installations under division control have been consistently excellent and have provided the staff sections concerned with information and advice essential to the completion of their various missions. The high standard of sanitation now found in all our units is in itself a tribute to your conscientious and capable work." Dr. Bretz was also awarded the Purple Heart. He is a graduate of the Indiana University School of Medicine and entered the service July 1, 1942.

Captain David M. Clough

The Bronze Star was recently awarded to Capt. David M. Clough, M. C., U. S. Army, of Los Angeles, for meritorious achievement in the performance of services during the period April 15 to October 1, 1944. "When assuming complete responsibility for the malarial control program in San Severo, Italy, area," said the citation, "he performed his task far beyond the requirement of ordinary duty, overcoming almost insurmountable difficulties relative to supply, personnel and motor transportation. Captain Clough's outstanding supervision and direction of the Italian laborers was a difficult task, being handicapped in not speaking the native language. His tenacity of purpose resulted in the eradication of all serious mosquito breeding reservoirs dangerous in this area. As a result only 1 case of malaria developed in this area during the past season. Captain Clough's initiative and organizational ability were definite contributions in protecting the health of a countless number of troops from contracting malaria. His manner of execution of his duties reflect great credit on himself and the armed forces of the United States." Dr. Clough graduated from the University of Minnesota School of Medicine in 1942 and entered the service Aug. 9, 1943.

MISCELLANEOUS

THE IMPROVED VOCATIONAL REHABILITATION PROGRAM

The director of the Office of Vocational Rehabilitation, Michael J. Shortley, Washington, D. C., has announced that the states and the federal government have set a goal of 150,000 for civilians to be rehabilitated into employment each year, almost four times the number prepared and placed in suitable occupations in any one year to date. Budgetary estimates of the states indicate that there is a minimum of 1,168,000 physically or mentally handicapped persons of working age—not including veterans with service connected disabilities—in need of vocational rehabilitation services. Every state in the Union operates a civilian vocational rehabilitation program with the assistance of the federal government, Shortley said. The state appropriations, now more than 5 million dollars a year, were increased 60 per cent the only time the state legislatures met since the Rehabilitation Act was liberalized in 1943.

The District of Columbia, Hawaii and Puerto Rico, in addition to the forty-eight states, operate vocational rehabilitation programs, and Alaska will inaugurate one soon. Separately administered programs exist for the blind in thirty-six states, and in the other states and territories the blind are provided services by the regular rehabilitation agencies. The state rehabilitation agencies prepare disabled individuals for the type of employment for which their ability and talents give them opportunity for successful employment. Shortley said "Some clients go to college, others attend business and trade schools, still others develop their skills in training on the job. All clients are medically diagnosed and, where necessary, are provided with physical restoration to remove or reduce the effects of the disability. Training is provided as needed. In each instance counseling and guidance continue until satisfactory performance on the job justifies closing the case."

The average number of rehabilitations into employment has risen from 9,100 a year before passage of Public Law 113 to more than 40,000 a year after passage, an increase of better than 400 per cent.

The amendments of 1943 to the original vocational rehabilitation act made possible the improvements in service. These amendments provided full medical, surgical and psychiatric services to remove or reduce the disability, whereas before 1943 the rehabilitation agencies had been forced to train around the disability, without attempting to alleviate it. The amendments also extended stronger federal financial support to the state agencies and thus stimulated many of them to greater activity.

The improved vocational rehabilitation program, Shortley said, is eliminating a great amount of dependence. It costs $300 to $600 a year to maintain a disabled person. It costs, on an average, $300 to rehabilitate him. Second, the program is increasing the productive manpower of the nation. About 75 per cent of the 1946 rehabilitants were unemployed at the time the states started services. About 16 per cent of the rehabilitants had never worked before.

INSTITUTE OF INTER-AMERICAN AFFAIRS

The Training Division of the Institute of Inter-American Affairs, under the direction of Dr. William W. Peter, reports that 99 public health trainees were in the United States as of October first of this year to carry on studies during the academic year 1946-1947, including 88 men and women here on regular study grants: 20 engineers, 38 doctors (2 women), 25 graduate and undergraduate nurses, 1 statistician, 1 laboratory technician, 1 hospital records clerk, 1 laundry manager and 1 dietitian. These public health trainees represent thirteen South and Central American republics: Brazil 44, Bolivia 11, Chile 6, Columbia 9, El Salvador 4, Nicaragua 4, Guatemala 6, Peru 5, Costa Rica 3, Ecuador 1, Mexico 2, the Dominican Republic 2 and Venezuela 2.

As of October 1, 559 Public Health Fellows from eighteen countries had come to the United States under the Institute of Inter-American Affairs Health and Sanitation training program since its inception, July 1, 1944.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

First M.D. Degrees Awarded in Twenty-Six Years.—The Medical College of Alabama held its first annual commencement in Birmingham, October 25. According to Barbara Tucker, director of public relations of the medical school, representatives of the medical profession, state and national government, education and civic groups were in attendance to mark the first time in twenty-six years that M.D. degrees had been awarded in Alabama. The Medical College of Alabama opened officially June 4, 1945 with instruction in a junior class, and on October 8 of the same year the school of basic medical sciences on the university campus, established in 1920, where first and second years were given, was absorbed into the medical school. On this occasion the school of basic sciences ceased to exist. It was the direct successor in 1920 to the Medical College of Alabama at Mobile, organized in 1859. The new Medical College of Alabama was established by action of the 1943 state legislature as a division of the University of Alabama. It was located in Birmingham in 1944 by vote of a special governor's commission (THE JOURNAL, Aug. 11, 1945, p. 1116).

ARKANSAS

Henry Chenault Named Dean.—Dr. Henry C. Chenault, Hot Springs, has been appointed a vice president of the University of Arkansas and dean of the medical school, Little Rock. In the latter position Dr. Chenault will succeed Dr. Byron L. Robinson, Little Rock, who resigned, effective October 1, but who has agreed to remain with the school until January 1. Dr. Chenault graduated at Arkansas in 1927.

CALIFORNIA

Bequest for Cancer Research.—The University of California Medical School, San Francisco, will receive a bequest valued at $592,065 to carry on research for a cure of cancer. The benefaction is made possible from the estate of the late Albert C. Hooper, Palo Alto philanthropist. The University of California *Clip Sheet* reports that Mr. Hooper's uncle George Williams Hooper and his wife, Mrs. Sophronia Hooper, were responsible for the establishment at the university of the Hooper Foundation for Medical Research.

COLORADO

Grants for Research.—A grant of $3,000 was presented to Bernard B. Longwell, Ph.D., associate professor of biochemistry, University of Colorado School of Medicine, Denver, by the Ciba Company, manufacturers of pharmaceuticals and dyestuffs in New York. Dr. Longwell, in collaboration with Frank X. Gassner, D.V.M., professor of animal pathology at Colorado State College of Agriculture and Mechanic Arts, Fort Collins, is working on the possible extraction of hormones from animal feces for use in the treatment of sterility in cattle. A grant also was made to Dr. Harry H. Gordon, professor of pediatrics, by the Mead Johnson Company, Evansville, Ind. Dr Gordon is studying the metabolism of premature babies.

ILLINOIS

Citizens Vote for Health Units.—Seventeen counties in Illinois voted favorably by heavy majorities, November 5, for the inauguration of full time county health units. The seventeen counties include one four county unit and three bicounty units. The proposition was lost only in Rock Island County, it was reported. Altogether twenty-two counties have now adopted county health department laws. When organized, two thirds of the population of the state will be under full time county and municipal health service. The seventeen counties voting recently are Alexander-Pulaski (bicounty unit), Effingham, Fulton, Hardin-Pope-Massach-Johnson (multiple county unit), Lawrence-Wabash (bicounty unit), Lee, Morgan, Peoria, Piatt-DeWitt (bicounty unit), Shelby and Will.

Experimental Study in Influenza Vaccine.—The Illinois State Department of Public Health and the Universities of Illinois and Northwestern and the state normal schools at Carbondale and DeKalb are cooperating in studies to determine the value of influenza vaccine. Students at the institutes are being offered the vaccinations on a voluntary basis. A comparison of the incidence of the disease in those who accept the vaccination and those who do not will help to establish the effectiveness of the influenza vaccine. In a statement to the press, Dr. Roland R. Cross, state director of public health, said that, although the department of public health is not able to offer free influenza vaccine to all, many physicians will no doubt wish to administer it to their private patients.

Chicago

Personal.—Dr. David J. Davis, recently retired as dean of the University of Illinois College of Medicine, on November 1 was elected chairman of the Municipal Tuberculosis Sanitarium, filling the vacancy that occurred with the resignation of Dr. Frederick Tice more than a year ago. Dr. Earl E. Kleinschmidt, head of the Tuberculosis Institute of Chicago and Cook County, was named secretary. Harry Reynolds was reelected vice president and will continue to serve as business manager.

Electrocardiographic Interpretation.—A course in electrocardiographic interpretation for graduate physicians will be given at the Michael Reese Hospital Postgraduate School by Dr. Louis N. Katz, director of cardiovascular research. The class will meet each Wednesday for twelve weeks, beginning February 12. Further information and a copy of the lecture schedule may be obtained on application to the office of the dean, Michael Reese Hospital Postgraduate School.

La Rabida Sanitarium Observes Fiftieth Anniversary.—The La Rabida Jackson Park Sanitarium observed its fiftieth anniversary October 15 by launching a "research drive" aimed at discovering the cause and prevention of rheumatic fever. A fund of $37,500 was pledged or donated to carry on the study, which will be under the supervision of the sanitarium medical director, Jesse W. Hofer, Ph.D. It is hoped to establish six fellowships in the medical schools of Chicago, Northwestern, Illinois and Loyola, as well as in the laboratory of the sanitarium.

Changes in Northwestern Faculty.—Ray S. Snider, Ph.D., for twenty-six months senior pathologist and biologist with the atom bomb project at Oak Ridge, Tenn., and senior monitor and pathologist of Joint Task Force I at Bikini, has been appointed associate professor of anatomy at Northwestern University Medical School. Dr. Jules H. Masserman, assistant professor of psychiatry and research associate, Otho Sprague Institute, University of Chicago, has been named assistant professor of nervous and mental diseases and John M. Brookhart, Ph.D., assistant professor of physiology, University of Illinois College of Medicine, has been named assistant professor of neurology, effective January 1.

Research Fellowships.—The Graduate School of the University of Illinois has established four research fellowships to be awarded for one year in the fields of medicine, dentistry and pharmacy in Chicago at a stipend of $1,200 a year (calendar year with one month's vacation). Fellows are eligible for reappointment in competition with the new applicants. Candidates for these fellowships must have completed a training of not less than eight years beyond high school graduation. Candidates should indicate the field of research in which they are interested and submit complete transcripts of their scholastic credits, together with the names of three former science teachers as references. Appointments will be announced January 1 or soon thereafter each year. The fellowship year begins September 1 or July 1. Formal application blanks may be secured from the Secretary of the Committee on Graduate Work in Medicine, Dentistry and Pharmacy, 1853 West Polk Street, Chicago 12.

INDIANA

Hearing on "Diabetic Institute."—On October 12 Dr. Peter S. Kaadt, at present head of the Kaadt Institute, South Whitley, was cleared of charges of noncompliance with state hospital licensing requirements, according to the Indianapolis *News*. In answer to the charge that he had failed to obtain a license for the institute, Dr. Kaadt said he was conducting a private physician's practice and did not come under the purview of the council. Charges that he had kept bed patients in the building more than twenty-four hours and that he had been serving meals in conjunction with the treatment were termed incorrect by Dr. Kaadt. He said that practice had been discontinued when he first took charge July 31, the *News* reported. He said he did, however, make meals available for those who wished to stay. On the strength of investigation at the hearing Dr. Kaadt was advised by the Indiana Council for Hospital Licensure that, subject to the discontinuance of meal servings and the use of hospital bed facilities for treatment, he was not required to license the establishment. Charges have been levied against Dr. Charles F. Kaadt, brother of Dr. Peter Kaadt, for the administration of an alleged cure for diabetes at the institute. The Indianapolis Better Business Bureau, which has made the charges, alleges that several persons have died as a result of the treatment. Dr. Charles Kaadt, who is reported to be in Tennessee recovering from anemia (The Journal, October 5, p. 296), won a ninety day delay in the hearing of charges on maladministration of a "diabetes cure," the *Star* stated. The Indiana Council for Hospital Licensure is a new state board of health agency, created under the 1945 licensing act.

MARYLAND

Resolution Honors the Late Phillips Goldsborough.—The Maryland State Department of Health at its meeting October 24 adopted a resolution of sympathy on the death of Hon. Phillips Lee Goldsborough, acknowledging his leadership. The resolution states that during his term of office as governor he had frequent discussions with his brother, Brice W. Goldsborough of Cambridge, one of Maryland's leading practitioners and a former president of the Medical and Chirurgical Faculty of Maryland, relative to the bettering of the health conditions of the citizens of Maryland. Finally, the resolution points out, Governor Goldsborough introduced legislation some thirty years ago for the establishment of a deputy state health officer in each county. He was successful and eventually all counties had deputy state health officers assigned to them. Thanks to the wise statesmanship of Governor Goldsborough, Maryland was one of the first states in America to have full time deputy state health officers.

Reginald Archibald Named Professor of Biochemistry.—Dr. Reginald M. Archibald, associate at the Rockefeller Institute for Medical Research, New York, and special investigator at the hospital, has been appointed professor of biochemistry at the Johns Hopkins University School of Hygiene and Public Health, Baltimore, filling the vacancy created by the retirement of Elmer V. McCollum, Sc.D. Dr. Archibald will place primary emphasis on biochemistry as related to human nutrition, both in the laboratory and in actual practice. Graduate students at the school, along with Dr. Archibald and staff, will approach nutrition problems in the laboratory from the point of view of study of the influence of minerals, vitamins and hormones on the activity of enzyme systems in human beings and in organisms such as bacteria and larger parasites which infect man. This study, Dr. Archibald points out, will also call for the development of improved methods for the determination of hormones and vitamins. Mrs. Elmer V. McCollum, wife of the retired head of the department, will remain as assistant professor and will continue her work on studies of animal nutrition.

MASSACHUSETTS

Hugo Muench New Head of Biostatistics.—Dr. Hugo Muench, professor of biostatistics, Harvard University School of Public Health, Boston, has been appointed head of the department of biostatistics, it was announced November 8. Dr. Muench is also assistant dean. Dr. Muench was formerly a member of the staff of the International Health Division of the Rockefeller Foundation, New York.

The Dunham Lectures.—"Biochemical Lesions and British Anti-Lewisite" was the theme of the Edward K. Dunham Lectureship for the promotion of the medical sciences at Harvard Medical School, Boston, November 18, 20 and 22. In the series Dr. Rudolph A. Peters, Whitley professor of biochemistry, University of Oxford, England, discussed the significance of biochemical lesions, the arsenical lesion and its antidote, and clinical applications and development of BAL.

Meeting of Obstetrics and Gynecology Society.—The eighteenth annual meeting of the New England Obstetrical and Gynecological Society was held at the Hotel Somerset, Boston, October 30. Various clinics comprised the program, and speakers in an afternoon program included:

Dr. Alonzo K. Paine, Boston, The Posterior Occiput.
Dr. James C. Janney, Boston, The Doctor's Responsibility in Preparation for Marriage.
Dr. George V. S. Smith, Brookline, Discussion of Hormone Therapy in the Prevention of Miscarriage and Other Aspects of Pregnancy.

Fellowship Goes to Thomas Paine.—The American College of Physicians has awarded a research fellowship to Dr. Thomas F. Paine Jr., Cambridge, for the year beginning July 1. The fellowship provides for the continuation during this period of the study of infectious diseases, with *particular regard to* chemotherapy and the use of antibiotics, in which Dr. Paine is currently engaged at the Thorndike Memorial Laboratory, Boston City Hospital, under the supervision of Dr. Maxwell Finland. Dr. Paine graduated at Vanderbilt University School of Medicine, Nashville, in 1942. After his internship at the Strong Memorial Hospital, Rochester, N. Y., in 1943 he entered the Medical Corps, Army of the United States. From November 1945 to May 1946 Dr. Paine was assigned as Post Surgeon, CO Station Hospital, Camp Detrick, Frederick, Md., and there participated in clinical and laboratory studies of infectious diseases.

Psychiatric Department Expanded.—Boston University School of Medicine has expanded its department of psychiatry with six new appointments and one promotion. The appointments are:

Dr. John M. Murray, professor of clinical psychiatry.
Dr. George E. Gardner, associate professor of psychiatry.
Dr. Marian C. Putnam, instructor in psychiatry.
Dr. Beata Rank, assistant in psychiatry.
Dr. Benjamin Cohen, instructor in psychiatry.
Dr. Elvin V. Semrad, assistant professor in medicine (promotion).
Dr. Frederick Rosenheim, assistant professor of psychiatry.

As a part of the program of expansion the number of hours of psychiatric instruction has been more than doubled and students will begin their training in psychiatry in the first year. *Work of the department will be integrated with that of the* departments of internal médicine, surgery and pediatrics at the school of medicine and its affiliated hospitals. Students will visit the Judge Baker Center and the Children's Center as well as work in the wards with the patients.

Putnam Fellowship for Advanced Research.—Radcliffe College invities applications for the Helen Putnam Fellowship for Advanced Research. The committee on award would be interested in receiving nominations immediately from eligible women scholars who have research in progress in the field of genetics or of mental health, broadly defined. The fellowship will pay a stipend of $2,000, and the tenure of the fellowship will run for a term of eleven months from Oct. 1, 1947, with the possibility of a renewal for a similar period. All normal laboratory facilities will be provided to the holder of the fellowship. Each fellow will be assigned room and board (at cost) in one of the Radcliffe graduate houses and will be expected to be in residence during the tenure of the fellowship. No restrictions as to age will be imposed by the committee on award. In general, however, the committee will limit its choice to mature women scholars who have gained their doctorate or who possess equivalent qualifications. Applications for the award should be submitted to Radcliffe College not later than April 1, 1947 and the announcement of the appointment to the fellowship will be made on or about May 1, 1947. Application forms may be secured by addressing the Committee on the Helen Putnam Fellowship for Advanced Research, Radcliffe College, Cambridge 38, Mass.

MICHIGAN

State Medical Election.—Dr. Patrick L. Ledwidge, Detroit, was named president-elect of the Michigan State Medical Society at its recent meeting in Detroit, and Dr. William A. Hyland, Grand Rapids, was installed as president. Dr. L. Fernald Foster, Bay City, was reelected secretary.

Cancer Committee Expands.—Feeling that the time had arrived to coordinate as far as possible all cancer control activities so as to avoid duplication of effort and expense, Dr. William A. Hyland, Grand Rapids, president of the Michigan State Medical Society, has enlarged the cancer control committee this year to include the members of the Professional Executive Committee of the American Cancer Society, Michigan division, and representatives of the Michigan Department of Health. Under the chairmanship of Dr. Norman F. Miller, Ann Arbor, three subcommittees have been formed to study the *problems of lay and professional education, the collection and* disbursement of funds for cancer control and the extent of the cancer problem in Michigan together with the needs of local areas to render a more competent and adequate service to cancer patients. Dr. Frank L. Rector, a member of the Ingham County Medical Society, has been appointed as full time secretary with offices at 1313 East Ann Street, Ann Arbor. For the past five years Dr. Rector has been in charge of the cancer program of the Michigan Department of Health and has devoted most of his time to cancer education. The Michigan Department of Health has been allocated $86,000 of federal funds through the U. S. Public Health Service this year for cancer control activities in this state. The American Cancer Society, Michigan division, also will have greatly increased funds at its disposal. The cancer control committee will help plan *programs and expenditure of these funds as well as offer a* general information service on cancer problems in Michigan and elsewhere. As far as known, the Michigan State Medical Society is the first state medical society to employ a full time medically trained secretary to carry on its cancer control activities.

MINNESOTA

Students in Experiment to Study Aging Process.—The University of Minnesota, Minneapolis, is using 400 persons as voluntary "guinea pigs" to determine the process of aging of man. Half of the group will be university students between 18 and 20 years whose homes are in Minneapolis and St. Paul, while the other half are men between 45 and 60. The experiment will be under the direction of Ancel B. Keys, Ph.D.

Change in Constitution for Surgical Membership.—On October 3 the Minneapolis Surgical Society amended its constitution to read that candidates for active membership must be practicing in Minneapolis, must have graduated in 1936 or thereafter, must first be certified by the American Board of Surgery, must be fellows of the American College of Surgeons in good standing, limiting their practices to general surgery, and must have published at least one surgical paper in a resognized medical journal. The old amendment that candidates for active membership must be practicing in Minneapolis and should only be fellows of the American College of Surgeons practicing general surgery or general surgeons who have fulfilled the minimum requirements of the American College of Surgeons and are limiting their practice to surgery shall be eligible for election as active members. Both the old and the new amendments provide that the active membership should be limited to fifty.

OHIO

Appointments in Mental Hygiene.—Dr. Mark W. Garry, formerly of Milwaukee, since 1945 director of the tuberculosis division of the Ohio State Department of Health, has been appointed chief of tuberculosis and internal medicine in the division of mental hygiene, Ohio State Department of Public Welfare, effective October 16. Dr. Garry will be in charge of tuberculosis control and treatment in the institutions and will also be responsible for organizing the medical program of the institutions in the division. Miss Anna T. Lowine, R.N., director of the postgraduate school of psychiatric nursing, Menninger Sanitarium, Topeka, Kan., has been named chief of nursing service and education in the division of mental hygiene and Wallace C. Fotheringham, M.A., a member of the staff of Muskingum College, has been named chief of institutional personnel training.

Prentiss Award Goes to Mary Connolly.—The 1946 Elisabeth S. Prentiss National Award in Health Education will be presented to Miss Mary P. Connolly, Dushore, Pa., lecturer and director of health education, University of Michigan School of Public Health, Ann Arbor, for her "down to earth pioneering" in Detroit. The award committee recognized her pioneering in the organization of 15,000 women into the Mother and Daughter Council, work in the Detroit Evening Schools for the foreign born, development of health guilds (one for Negro women now has fifty-seven units in Negro churches), education for food handlers, neighborhood classes for child care, person to person education regarding venereal diseases, with pool rooms, bowling alleys and beer parlors for classrooms. Miss Connolly is one of the group instrumental in establishing and maintaining the health education institute held annually in connection with the annual public health association meeting. The presentation was announced November 13 at a dinner meeting of the American Public Health Association by Dr. William W. Peter, chairman of the National Advisory Council of the Cleveland Health Museum. November 13 was the sixth anniversary day of the museum's opening in 1940 and the tenth year since its incorporation in 1936. Elisabeth S. Prentiss, in whose honor the award was named, provided the original home and a substantial trust fund for the first health museum in America. Expanding activities due to requests from health educators throughout the world made a move to larger quarters necessary early this year (The Journal, February 16, p. 438).

WASHINGTON

New Health Department.—Bellingham and Whatcom County will probably enjoy the advantages of a full time health department by January 1 as the result of recent action by the city council and county commissioners, it is reported. A $60,000 budget is planned for the new department, which will replace the two part time departments now operated by the city of Bellingham and Whatcom County. The staff, to be headed by a full time health officer trained in public health, will total eighteen persons and include a nursing supervisor and nine public health nurses. Dr. Harrison Garner Wright is head of the present Whatcom County Health Department, while Dr. Calvin L. Longstreth is Bellingham city health officer.

The Health Commentator.—The Washington State Department of Health, Seattle, on October 15 brought out the *Health Commentator* as its official bulletin. Howard W. Lundy, Dr.P.H., is editor and Seymour Standish Jr. managing editor of the monthly bulletin.

State Medical Election.—Dr. Albert J. Bowles, Seattle, was chosen president-elect of the Washington State Medical Association at its recent meeting and Dr. Ross D. Wright, Tacoma, was installed as president. Other officers are Dr. Alexander H. Peacock, Seattle, vice president, and Dr. Harold E. Nichols, Seattle, secretary treasurer.

ALASKA

Health Departments Established.—The Anchorage City Council passed the first ordinance to create a city health department. On July 1 the city's health budget was increased and supplemented by funds from the Territorial Department of Health. It now provides for a full time sanitarian and an increase in the nursing staff from two to three nurses. In August the city of Fairbanks appointed its first medical health officer. This office in the past has been held by the chief of police. The venereal disease clinics, formerly conducted by a medical officer from the nearby army post, were moved to the city's health center. Monthly immunization clinics have also been added to the city's health services. The Juneau health center, which formerly occupied a small room in the Territorial Building, has been moved to a separate building with the aid of the Juneau Health Council.

GENERAL

Grant Aids Expansion of Journal.—The American Foundation of Tropical Medicine has obtained $3,800 to enlarge its journal temporarily. The bulk of the money, $3,000, was a grant from the Coolidge Foundation and will allow the publication to use a considerable number of papers concerning observations on the tropical diseases during World War II.

Special Society Election.—Dr. Clarence E. Van Epps, Iowa City, was chosen president of the twenty-fifth anniversary meeting of the Central Neuropsychiatric Association at its meeting in Denver, October 4-5. Other officers include Dr. Jack R. Ewalt, Galveston, vice president, Dr. William C. Menninger, Topeka, secretary-treasurer, and Dr. Abram E. Bennett, Omaha, counselor.

Proctologic Prize Goes to Harold Courtney.—The American Proctologic Society has awarded its annual Hermance Award to Dr. Harold Courtney, Syracuse, for "an outstanding scientific paper in the field." The paper was entitled "The Posterior Levator Space: Its Relation to Postanal Infections" and was presented before the 1946 session of the society at its meeting in San Francisco in June.

Accruals of Blood Service for Voluntary Hospitals.—On October 7 the trustees of the Blood Transfusion Association voted to make use of accruals resulting from the operation of the blood bank to provide the voluntary hospitals using the service with blood free of charge for indigent patients requiring transfusions. For the first months 150 units of blood have been placed at the disposal of the hospitals for this purpose. The Blood Transfusion Association, of which Dr. DeWitt Stetten is president, has offices at 2 West 106th Street, New York 25.

Council of Jewish Tuberculosis Institutions Dissolved.—The National Council of Jewish Tuberculosis Institutions was dissolved as of November 1. Communications regarding the individual member institutions should be sent direct to them at the following addresses:

Ex-Patients' Tubercular Home of Denver, 8000 East Montview Boulevard, Denver.
National Jewish Hospital at Denver, 3800 East Colfax Avenue, Denver.
Jewish Consumptive Relief Association, 208 West 6th Street, Los Angeles 14.
Committee for Care of Jewish Tuberculous (Altro Work Shops), 71 West 47th Street, New York.
Deborah Sanatorium, Browns Mills, N. J.
Winfield Sanatorium, Winfield, Ill.
Montefiore Hospital for Chronic Diseases, Gun Hills Road, New York.
Montefiore Hospital Country Sanatorium, Bedford Hills, New York.

Graduate Course for American Physicians.—Dr. Julian Landman, 62 Queen Anne Street, London, England, arrived in New York October 21 to arrange postgraduate courses in London for American physicians. Dr. Landman's address while in New York is care of the City Farmers Bank Trust Company, 22 William Street. According to a communication from

Dr. Landman arrangements have been made with postgraduate hospitals and teachers in London to provide postgraduate tuition in clinical medicine, surgery, ophthalmology and ear, nose and throat diseases. For these general courses there will be vacancies for about fifty members during each of the months of May, June, July, August and September 1947. In correspondence to the editor, the *British Medical Journal*, September 7, page 345, published a letter from Dr. Landman discussing the proposed postgraduate courses.

Lasker Awards.—Presented to the American Public Health Association by the Albert and Mary Lasker Foundation, the first series of Lasker Awards for advances made during the past five years were presented at the seventy-fourth meeting of the public health association in Cleveland, November 12. The awards consist of five individual awards of $1,000 each together with a gold statuette of the Winged Victory of Samothrace, symbolizing a victory in the fight against disease and death. During the deliberations of the awards committee it became evident that methods of medical research are changing to such an extent that the manner of recognition must be changed or broadened. Some important discoveries in medicine in the past few years were not the work of a single man but of large groups of men and women working together against time to solve a specific problem. For that reason the committee decided to add five group awards to the originally planned individual awards. These awards are in the form of a citation and a Winged Victory statuette in silver presented to the administrative leader of the group. As in the case of the individual awards, these statuettes will be suitably inscribed on the base. The first individual award winner is Dr. Carl F. Cori, St. Louis, for contributions to our knowledge of carbohydrate embolism culminating in the clarification of insulin action. Dr. John F. Mahoney, a senior surgeon, U. S. Public Health Service, stationed at the U. S. Marine Hospital, Staten Island, N. Y., received an award for research into the penicillin treatment of syphilis. Dr. Mahoney is credited with publishing three years ago the first account of the use of penicillin in the treatment of syphilis. One award went to three men jointly who were responsible for the discovery of the Rh factor. These recipients are the late Dr. Karl Landsteiner, the honor to be received by his son Ernest; Dr. Philip Levine, Plainfield, N. J., director of the biologic division, Ortho Research Foundation, Linden, N. J., and Dr. Alexander S. Wiener, Brooklyn. Dr. Alfred N. Richards, professor of pharmacology, University of Pennsylvania School of Medicine, Philadelphia, received the award for his work in World War II as chairman of the committee on medical research of the U. S. government's Office of Scientific Research and Development. Dr. Fred L. Soper, associate director of the international health division, Rockefeller Foundation, received the fifth of the individual Lasker awards for his successful fight against malaria and yellow fever. In presenting the Lasker group awards the committee had some difficulty in getting representatives of the five groups to accept the awards. In each case the director of the group felt that no one man was in a position to accept such an honor, for the contribution that had been made was a result of the combined efforts of many men and women working together. However, representatives of the groups were prevailed on finally to accept the silver statuette. The first group to receive a silver statuette is the Bureau of Entomology and Plant Quarantine of the United States Department of Agriculture for its work in controlling insect borne diseases and particularly for its research on DDT. Fred C. Bishopp, Ph.D., assistant chief of the bureau, will accept the award in the name of the group. The Army Epidemiological Board is the second winner of a Lasker group award for its work in the control of infectious diseases, one aspect of which was its development of an effective vaccine against influenza. Dr. Francis G. Blake, dean of the Yale University School of Medicine, New Haven, was the chairman of the group and will accept the award. The National Institute of Health of the U. S. Public Health Service is the third winner of a Lasker group award. This organization is the research laboratory of the U. S. Public Health Service. Dr. Rolla E. Dyer, director of the institute, will accept the award for the group. The Northern Regional Research Laboratory of the Department of Agriculture is the recipient of the fourth Lasker group award, being given for studies leading to the mass production of penicillin. Dr. Guido E. Hilbert, present director of the laboratory, will accept the award for this group. The final Lasker group award went to the Board for the Coordination of Malarial Studies for its work leading to the development of new and effective agents for the prevention of malaria.

CANADA

New Professor of Gynecology at Toronto.—Dr. Herman B. Van Wyck, Toronto, Ont., has been appointed professor of gynecology and obstetrics at the University of Toronto Faculty of Medicine, succeeding Dr. William A. Scott, who is retiring. Dr. Scott will continue in private practice and as main board examiner in the medical council of Canada.

University News.—Louis B. Jaques, Ph.D., has resigned from the department of physiology, University of Toronto Faculty of Medicine, Ontario, to become professor and head of the department of physiology, University of Saskatchewan, Saskatoon, Canada. The medical school has been reorganized and will from now on give a full four year course.

Grant for Research in Endocrinology.—A grant of $47,000 has been made to the Institute of Experimental Surgery and Medicine, University of Montreal, Quebec, to assist in the work of Dr. Hans Selye, who recently organized the department of endocrine research as professor and director of the institute. Dr. Selye, whose work has been concentrated on the steroid field, received his M.D. at the University of Prague in 1929. In 1931 he worked in the department of biochemical hygiene at the Johns Hopkins University School of Medicine, Baltimore, under a Rockefeller research fellowship.

The Charles Mickle Lecture.—Bernardo A. Houssay, professor of physiology, University of Buenos Aires, delivered the annual Charles Mickle Lecture, September 19, on "Alloxan Diabetes." Dr. Houssay delivered the lecture in his holding of the Charles Mickle Fellowship, which he was awarded in 1945. The fellowship is given annually by the University of Toronto Faculty of Medicine to "that member of the medical profession who is considered by the council of the faculty of medicine to have done most during the preceding ten years to advance sound knowledge of a practical kind in medical art or science."

Immunization Week.—The Health League of Canada announced that the fourth National Immunization Week was observed during the week beginning September 29. The league reports that there was an improvement in the general overall health picture in Canada. For instance, there were 2,786 cases of diphtheria in 1945 against 3,211 in 1944, 11,928 cases of scarlet fever against 20,945 and 12,192 cases of whooping cough against 12,382. Statistics on deaths are available for only the first nine months of 1945, and, with the exception of whooping cough, the fatality rate from these particular diseases also shows a drop. However, there were 325 whooping cough deaths in the first nine months of 1945 compared with 333 for all of 1944.

CORRECTION

Woman's Medical College of Pennsylvania.—In the State Board Number of The Journal, May 11, 1946, page 111, the percentage of failures of graduates of the Woman's Medical College of Pennsylvania before medical licensing board examinations was reported as 15.0. One candidate was successful in New York but applied too late for the anatomy and physiology examination and was reported among the failures. In computing the state board statistics the procedure is to omit incomplete examination results. Thus the percentage of failures for this school should have been 10.5. Of the 19 graduates examined, 2 failed.

Marriages

James Austin Davis Jr., Bessemer, Ala., to Miss Mary Katherine Pappandreou of Fredericksburg, Va., July 1.

Kenneth Hill Herbert, Mount Pleasant, S. C., to Miss Stella Virginia Pope of Dade City, Fla., June 20.

Frank Cutchin Bone, Rocky Mount, N. C., to Miss Margaret Leigh Lowrance of Durham, July 6.

Moylan Bernard Kehoe, Flint, Mich., to Miss Eileen Elizabeth O'Brien in Normandy, Mo., in June.

James Andrew Clark Jr., Ruleville, Miss., to Miss Margaret Ellen Smith of Amite, La., June 5.

Howard Hunter Nichols, Nashville, Tenn., to Miss Betty Jane Martin of Jackson, Miss., July 1.

William C. Van Buskirk, Boston, to Miss Vivian Morton of Warrensburg, Mo., in June.

Joseph Stuart Staley to Miss Dorothy Maxine Thomas, both of Marion, Va., May 31.

Deaths

Hatch Whitfield Cummings, Hearne, Texas; University of Tennessee Medical Department, Nashville, 1892; born in Aberdeen, Miss., Sept. 14, 1869; member of the American Medical Association and in 1930 a member of its House of Delegates; past president and for many years a member of the Texas State Board of Medical Examiners; past president, chairman of the section on state medicine and public hygiene in 1910 and again in 1919, at one time a member of the committee on legislation and public instruction, and councilor of the Eleventh District in 1906-1907 and 1907-1908, State Medical Association of Texas; one of the organizers and first president of the Brazos Valley Medical Association in 1896; a charter member of the Brazos-Robertson Counties Medical Society, which he served as president from 1927 through 1931; member of the state board of health from 1909 to 1911; health officer; for many years president of the school board; served as president of the Hearne Building and Loan Association, the Planters and Merchants State Bank and the Chamber of Commerce; for many years served as local surgeon for the Missouri Pacific and Southern Pacific railways; died July 29, aged 76, of arteriosclerosis.

Warren Kidwell Stratman-Thomas, Madison, Wis.; University of Wisconsin Medical School, Madison, 1928; born in Dodgeville, Wis., June 19, 1894; at one time assistant bacteriologist and research pharmacologist at the University of Wisconsin; in 1928 made a study of sleeping sickness in the Belgian Congo under a special fellowship created by the Guggenheim Memorial Foundation, the University of Wisconsin and the Parke Davis Laboratories; formerly member of the staff of the International Health Division of the Rockefeller Foundation and director of the bureau of malaria control at Nicosia, Cyprus; served as malariologist for the Tennessee State Department of Health and as assistant professor of preventive medicine at the University of Tennessee College of Medicine in Memphis; served during World War I and with the tropical medical service of the navy during World War II; at one time affiliated with the Florida State Board of Health; died in St. Mary's Hospital August 16, aged 52.

Theodore Lasater Terry ® Boston; University of Texas School of Medicine, Galveston, 1922; born in Ennis, Texas, on Feb. 19, 1899; assistant professor of ophthalmology at the Harvard Medical School and the graduate school; at one time on the faculty of his alma mater; diplomate of the National Board of Medical Examiners; specialist certified by the American Board of Ophthalmology, of which he had been assistant secretary; member of the American Academy of Ophthalmology and Otolaryngology, American Association for the Advancement of Science, and American Ophthalmological Society; member, past president and secretary of the New England Ophthalmological Society; member and trustee of the Association for Research in Ophthalmology; on the staffs of the Massachusetts General Hospital and the Massachusetts Eye and Ear Infirmary; elected president of the Foundation for Vision, of which he had been one of the founders; died September 28, aged 47.

Frank Wilson Jr., Raleigh, N. C.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1932; born in Greenville, N. C., June 30, 1909; served an internship and residency at the University Hospital in Baltimore and a residency at the Baltimore City Hospitals; received additional training at the U. S. Marine Hospital in Baltimore; member of the American Medical Association; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; began active duty as a captain in the medical corps, Army of the United States, on July 21, 1942; service terminated in July 1946 with the rank of major; on the staffs of the Rex and St. Agnes hospitals; consulting surgeon of the State Hospital and the Seaboard Air Line Railroad; member of the Raleigh Rotary Club; died in the Duke Hospital, Durham, September 22, aged 37, of influenza and encephalomyelitis.

Joseph C. Anderhub, Chicago; Ludwig-Maximilians-Universität Medizinische Fakultät, Munich, Bavaria, Germany, 1889; St. Louis College of Physicians and Surgeons, 1892; died at the Little Sisters of the Poor August 23, aged 83, of generalized arteriosclerosis.

Robert Vivian Baker, Camarillo, Calif.; Rush Medical College, Chicago, 1922; member of the American Medical Association; affiliated with the Camarillo State Hospital; died August 25, aged 52, of coronary occlusion.

Joseph Rolla Baldwin, Des Moines; University of Pennsylvania Department of Medicine, Philadelphia, 1898; died August 31, aged 83, of cerebral hemorrhage.

Richard Francis Barrett, Shrewsbury, Mass.; University of Bishop College Faculty of Medicine, Montreal, Que., Canada, 1904; died August 13, aged 75, of myocardial degeneration.

Arthur Clifton Conro, Attleboro, Mass.; Chattanooga (Tenn.) Medical College, 1901; member of the American Medical Association and the New England Otological and Laryngological Society; died in Boston July 18, aged 76, of carcinoma of the liver.

Mary Fisher DeKruif, Wellesley, Mass.; University of Michigan Medical School, Ann Arbor, 1916; affiliated with Simpson Infirmary of Wellesley College; died May 8, aged 57, of carcinomatosis.

William Alva Earle, South Brooksville, Maine; Bennett College of Eclectic Medicine and Surgery, Chicago, 1879; died in Brookline, Mass., March 26, aged 88, of cerebral arteriosclerosis.

William Henry Greeley, Weymouth, Mass.; College of Physicians and Surgeons, Boston, 1884; died in Holbrook April 3, aged 87, of mitral regurgitation.

Edwin Ball Hailey ® Conroe, Texas; University of Texas School of Medicine, Galveston, 1932; interned at the John Sealy Hospital in Galveston; president and formerly secretary of the Montgomery County Medical Society; died July 16, aged 40.

Ralph Ritter Higgins, Fall River, Mass.; Boston University School of Medicine, 1946; commissioned a lieutenant (jg) in the U. S. Naval Reserve; served an internship at the Medical College of Virginia, Hospital Division, in the capacity of a rotating intern at the Raiford Hospital in Franklin, Va., where he died July 27, aged 25, of injuries received in an automobile accident.

William Howe, Las Vegas, N. M.; Baltimore Medical College, 1898; member of the American Medical Association; died in July, aged 73.

George Franklin Jewett, White Salmon, Wash.; Starling Medical College, Columbus, 1882; died in Portland, Ore., September 20, aged 88.

Joseph Francis Kenney, Milwaukee; Milwaukee Medical College, 1908; on the staffs of St. Joseph's and West Side hospitals; affiliated with the Veterans Administration; died September 18, aged 60, of dissecting aneurysm of the aorta due to arteriosclerosis.

Joseph V. Kofron, Cleveland; Western Reserve University Medical Department, Cleveland, 1893; member of the Cleveland Academy of Medicine; affiliated with the Cleveland Medical Library Association, of which he had been a founder; for many years on the staff of St. Alexis Hospital; died in Chagrin Falls, Ohio, September 20, aged 76, of cerebral hemorrhage and asthmatic bronchitis.

Paul Lilja Lane, Chicago; University of Illinois College of Medicine, Chicago, 1941; interned at the Augustana Hospital; also a graduate in dentistry; died in Framingham, Mass., July 13, aged 48.

George Franklin Libby, Fillmore, Calif.; Medical School of Maine, Portland, 1891; honorary member of the Colorado State Medical Society; member of the American Medical Association and the American Ophthalmological Society; formerly secretary of the Colorado Ophthalmological Society; served on the staffs of the Mercy and St. Anthony's hospitals in Denver and the Sanatorium of the Jewish Consumptives' Relief Society in Spivak; died in a local hospital September 13, aged 78, of heart disease.

Edward Daland Lovejoy, Salem, Mass.; University of Pennsylvania Department of Medicine, Philadelphia, 1904; served as clinical professor of medicine (dermatology) at the University of Southern California School of Medicine and professor of clinical dermatology at the College of Medical Evangelists, both in Los Angeles; died March 24, aged 70, of carcinoma of the lungs.

Joseph Lutkiewicz, Chelsea, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1929; died July 16, aged 58, of pulmonary tuberculosis.

Michael Joseph McIntee, Holyoke, Mass.; Columbian University Medical Department, Washington, D. C., 1899; died in Northampton April 22, aged 78, of generalized arteriosclerosis.

Alice Woodby McKane, Boston; Woman's Medical College of Pennsylvania, Philadelphia, 1892; died March 6, aged 83, of arteriosclerosis.

Lena Augusta Geraldson Miller ⊕ Napa, Calif.; Cooper Medical College, San Francisco, 1903; for many years affiliated with the Napa State Hospital in Imola; died August 14, aged 72, of coronary thrombosis.

Thomas Francis O'Brien ⊕ Worcester, Mass.; Harvard Medical School, Boston, 1921; member of the New England Obstetrical and Gynecological Society; fellow of the American College of Surgeons; on the staffs of the Worcester City and St. Vincent hospitals; consulting obstetrician, Harrington Memorial Hospital, Southbridge, and the Webster District Hospital in Webster; died September 16, aged 51, of coronary thrombosis.

Herbert G. Perry ⊕ Louisburg, N. C.; College of Physicians and Surgeons, Baltimore, 1915; served as chairman of the county board of education and member of the county board of health; past president of the Franklin County Medical Society; owned the Louisburg Hospital; died in September, aged 57, of heart disease.

Albie Warren Sylvester, Pittsfield, Mass.; Medical School of Maine, Portland, 1892; member of the American Medical Association; died June 20, aged 83, of cerebral hemorrhage.

Arthur James Joseph Sullivan, Fall River, Mass.; Jefferson Medical College of Philadelphia, 1912; member of the American Medical Association; died August 6, aged 57, of myocarditis.

Luella Stone Swauger ⊕ Oakland, Calif.; California Medical College, San Francisco, 1892; died September 15, aged 74, of cerebral hemorrhage and hypertension.

John Webb Vaughn, Bergey, Pa.; Medico-Chirurgical College of Philadelphia, 1895; served during World War I; formerly member of the Pennsylvania Boxing Commission; president of the medical staff of the Elm Terrace Hospital, Lansdale; died September 24, aged 72.

Claud Earnest Watson, Dallas, Texas; University of Texas School of Medicine, Galveston, 1919; member of the American Medical Association; at one time assistant city health officer and an instructor of psychology at his alma mater; died in St. Paul's Hospital July 21, aged 55, following an operation for gallstones and obstruction of the bowels.

Isabel Gray Weston, Wellesley, Mass.; Boston University School of Medicine, 1887; died in Natick, July 19, of a fractured right femur.

Thomas Spaulding Williams, Dallas, Texas; Southern Methodist University Medical Department, Dallas, 1912; member of the American Medical Association; during World War I served overseas in the British army; an assistant surgeon in the U. S. Public Health Service; member of the staffs of the city board of health, St. Paul Hospital and Methodist Hospital, where he died July 18, aged 55, of coronary occlusion.

LIEUT. JOSEPH L. HALL
M. C., A. U. S., 1913-1944

LIEUT. COL. GEORGE T. COLVARD

LIEUT. EDWARD F. RITTER JR.
(MC), U. S. N., 1909-1944

KILLED IN ACTION

Joseph Leslie Hall, Stanton, Texas; University of Texas School of Medicine, Galveston, 1938; member of the American Medical Association; interned at the Robert B. Green Memorial Hospital in San Antonio; began active duty as a first lieutenant in the medical corps, Army of the United States, on Sept. 2, 1941; taken prisoner by the Japanese on the fall of Bataan in 1942 and remained in custody of the enemy until his death; awarded posthumously the bronze star medal for meritorious achievement while in a military prison camp in the Philippine Islands; died Oct. 24, 1944, aged 31, 200 miles off the coast of China, when the Japanese ship on which he was a prisoner was sunk by submarine action.

George Todd Colvard ⊕ Deming, N. M.; Medical College of Virginia, Richmond, 1924; interned at City Home Hospital, Richmond, Va., and St. Francis Hospital in Jersey City; past president of the New Mexico Medical Society and the president of the Luna County Medical Society; served as a county health officer; chairman of the board of the Carrie Tingley Hospital for Crippled Children in Hot Springs; surgeon for the Santa Fe Railway and the Southern Pacific Railway; began active duty as a major in the National Guard, 200th Coast Artillery (AA) in 1941; later promoted to lieutenant colonel; awarded the Bronze Star Medal posthumously; his unit received two citations in its withdrawal to Bataan; killed at Mindanao, P. I., when a Japanese freighter loaded with American prisoners of war was sunk by an American submarine Sept. 7, 1944, aged 49.

Edward Francis Ritter Jr., ⊕ Passed Assistant Surgeon, Lieutenant, U. S. Navy, Mattoon, Ill.; Northwestern University Medical School, Chicago, 1938; interned at the Jersey City Hospital in Jersey City; served a residency in ophthalmology at the Passavant Memorial Hospital in Chicago; entered the U. S. Navy in March 1939 and was stationed at the Naval Hospital in Brooklyn; later sent to the Philippines, where he was a prisoner of the Japanese; killed in action in the Asiatic area Oct. 24, 1944, aged 35.

The Need for Creating a Profession of Child Care

In a communication to the *Times* James Young, professor of obstetrics at the British Postgraduate Medical School, refers to the report of the chief medical officer of the Ministry of Health, which shows that during the war years there was a definite fall in the stillbirth rate and a considerable decrease in the deaths of the newborn. This he attributes chiefly to the better average nutrition of mothers resulting from higher wage levels, rationing and food priorities and supplements ordained under the food control system. Healthier mothers produced healthier babies despite factors operating against family stability, such as women's wholesale entrance into industry and damage from bombing. In the postwar years, with the risk of lowered economic standards and shortage in foods essential to expectant mothers, especially milk, Professor Young holds that it is the duty of the administration to maintain the highest possible level of food priorities and supplements. But this is not enough. We require a higher standard of child care. In countries more enlightened in child welfare, such as New Zealand and the Netherlands, personnel are specially trained for such home duties. In these countries the standard of mothercraft is much higher and the wastage of infant life is much lower than in our own. The minister of education recently stated that never in the history of education had there been such an overwhelming demand from all types of people for help in running the home. Professor Young thinks that the time is ripe for the creation of a profession of child care in its various grades—child nurses for private and public nurseries and institutions, teachers and administrators in child care. The professions of medicine, teaching and sick nursing have each their standards of training and diplomas. There are colleges, centrally controlled and state aided, for domestic science; but, for the women who wish to learn the greatest of all domestic sciences and arts, those relating to child care, facilities and encouragement do not exist.

Department of Medical Photography at Hospital

A new departure has been made by the Westminster Hospital, which has established a department of medical photography under the full time charge of a physician. One part of the work is to help in clinical investigation by enabling the staff to keep permanent visual records and to compare serial studies. It also helps in the teaching of students. Thus a film on inflammation has been made and other films are in preparation. For tutorial teaching photographic displays, for example one on gout, are arranged, and the film strip replaces the lantern slide. With a projector, pictures of any magnification which the light allows are reproduced on a screen.

The Centenary of the Discovery of Anesthesia

The centenary of the discovery of anesthesia is being celebrated. At the Wellcome Historical Museum there was an exhibition arranged in an instructive way by means of originals, reconstructions, models, photographs, diagrams and a large number of books. One show case illustrated the knowledge of narcotic and stimulating drugs in primitive times and among the Greeks and Romans, another the days of surgery without anesthesia; others the therapeutic uses of vapors and gases and ether frolics, inhalation anesthesia and nitrous oxide anesthesia.

The director of the museum, Dr. Ashworth Underwood, presided at a meeting in which Lord Moran, president of the Royal College of Physicians, delivered an address. He said that for ages people had tried to produce something which would permit operations being done without pain, but not until the nineteenth century was this achieved. It was left to Wells and Morton to bring it about. Wells apparently did everything necessary, but Morton had to put it across. Anesthesia was no accident but part of a great crusade. He looked with profound satisfaction on the fact that the democracies of Britain and America had taken the chief share in this humanizing process.

On the same day a meeting of the History of Medicine Section of the Royal Society of Medicine was held. Professor Charles Singer, medical historian, presided. He said that it was an error to suppose that before 1846 operations were always performed on the fully conscious. Narcotics and analgesics were known early. They were mentioned in Egyptian writings and in the hippocratic collection. They were mainly of the natural order Solanaceae. In the middle ages the main narcotics were opium, mandrake or belladonna, chiefly the leaves, and hyoscyamus or henbane. Hypnotism was first used in surgical operations by John Elliotson (1791-1862).

CHILE

(From Our Regular Correspondent)

Oct. 1, 1946.

Meeting of Radiologists

The Sociedad de Radiología of Chile, which was established in 1943, held a meeting in Santiago de Chile, September 15 to 17. From now on a meeting will be held each year. The society met in 1944 and 1945 in Santiago, Valparaiso and Concepción. The 1946 meeting was of unusual importance, and there was a large attendance. The official topic was the x-ray diagnosis of pulmonary diseases, and that of the first session was bronchiectasis, pulmonary abscess and silicosis. Drs. F. Daza and A. Toledo, head and assistant head respectively of the Department of Radiology of the Hospital Salvador, and Drs. W. Koch and E. Bellolio were official speakers. Dr. Daza spoke on x-ray semeiology, pathogenesis and anatomic interpretation of bronchiectasis. Dr. Toledo spoke on the differential x-ray diagnosis of circumscribed pulmonary suppuration either of long duration or shortened by the treatment. Drs. W. Koch and E. Bellolio spoke on radiologic diagnosis of pulmonary silicosis. The incidence of industrial silicosis is very high in Chilean industrial centers. In the afternoon Dr. O. Riedel, head of the Institute of Radiology of the San Francisco de Borja Hospital, spoke on the nomenclature of pulmonary diseases. The terminology for designating the different pulmonary lesions encountered during x-ray examination should be unified for a better coordination of studies and results. The speaker described the images he has observed most frequently in pulmonary tuberculosis. Dr. S. Calderón, head of the x-ray department of the National Department for Medical Care of Employees, discussed various aspects of the establishment of a department of preventive medicine. Dr. J. Gundelach, head of the x-ray Department of the Hospital de Tisiología, discussed the organization of a hospital for patients with tuberculosis. The third session was divided into two subsections. Dr. M. Riera, assistant of the Institute Heegewaldt, spoke on x-ray diagnosis of acute pulmonary diseases, based on x-ray observations in cases of lobar pneumonia. The favorable effect of modern chemical therapy is shown in the x-ray images of patients with lobar pneumonia in the course of the treatment. Dr. C. Velasco, assistant in the department of radiology of the Hospital Militar of Chile, spoke on x-ray diagnosis of virus pneumonia. The second subsection was held in association with the Sociedad Chilena de Gastroenterología. Dr. Fernán Díaz, assistant of the Instituto Heegewaldt, spoke on early x-ray diagnosis of gastric cancer, with special reference to cases simulating ulcer. At the closing session on September 17 Dr. L. Guzmán spoke on general indications for roentgen therapy and curietherapy. Other speakers were Dr. L. Opazo, professor of radiology of the Universidad Central, A. Larraguibel, dean of the Faculty of Medicine of the Universidad Central and Dr. R. Salas Pereira, president of the Sociedad Chilena de Radiología.

Correspondence

ARMY MEDICAL LIBRARY

To the Editor:—This is an earnest plea to all American physicians to support to the utmost the development of the Army Medical Library. Serving the profession in a more important way than any other single institution, this great library needs the personal interest and backing of all American physicians if it is to continue to maintain its activities in the manner expected of it. It is particularly important that American physicians support the effort of the Army Medical Library to acquire the permanent fireproof library building necessary to house its great treasures. Plans for such a building are in process, and a location for the new building has wisely been provided near the Library of Congress in Washington. This will assure maximum efficiency in the future development and use of the Army Medical Library for the benefit of the medical profession. It is important that individual physicians inform their representatives and senators of the importance of providing a safe and proper housing for the greatest medical library in the world.

Physicians are learning generally through hard experience that the successful practice of medicine requires continual study. The Army Medical Library is perhaps the single greatest factor in the United States in maintaining the standard of medical education, both for undergraduates and for postgraduates. It sets the standards for all medical libraries, whether established in medical schools, research institutions, county societies or academies. These libraries are the keynote to the entire medical educational effort. They all rely continually on the services of the Army Medical Library. This service can be extended to the mutual advantage of all concerned, through the enlightened interest and support of physicians and medical students. It is fortunate that the American Medical Association works so closely with the Army Medical Library. This cooperation makes possible the publication of the QUARTERLY CUMULATIVE INDEX and also of the great *Index Catalogue.* These are the necessary tools for the utilization of the tremendous body of medical literature now available for the student.

The Army Medical Library serves truly as a national medical library. However, it serves equally truly as a world medical library. The extent of its influence is clearly indicated by a recent English editorial (*Lancet* **2**:168 [Aug. 3] 1946). This editorial welcomed the receipt of the recent volumes of the *Index Catalogue,* so that English physicians may again have an opportunity to keep abreast of world literature in medicine. The editorial commented on the fact that the *Index Catalogue,* established by Dr. John S. Billings, is now in its fifty-sixth volume. It points out that 80 per cent of the issues are given freely to medical libraries in all parts of the world. The editorial goes on to comment on the wise guidance of Col. Harold W. Jones in maintaining the high quality of the *Index Catalogue.*

It may be possible for the Army Medical Library to extend its usefulness by establishing sublibraries in strategic parts of the country, such as on the West Coast, in the Middle West and in the South. Such sublibraries could contain microfilms of important periodical sets, together with duplicate material. Fortunately, medical libraries anywhere can continue to obtain assistance from the Army Medical Library in microfilms of otherwise inaccessible material. This service was one of the most important professional aids to our wideflung medical officers during the war.

It is necessary for the Army Medical Library to have ample funds for maintenance of its services and to be assured of the permanent fireproof building needed to house its great treasures. This building may become a center for basic research in all the health sciences. In order to obtain these funds it is essential that physicians generally show their representatives in Congress that they appreciate and need the continued service of the Army Medical Library. As William H. Welch indicated, the Army Medical Library still remains the greatest contribution of this country to medicine.

CHAUNCEY D. LEAKE, M.D., Galveston, Texas.
Vice President, University of Texas.

REACTION TO PENICILLIN

To the Editor:—In view of the good results that have been reported during the last eighteen months in the use of penicillin aerosol treatments for asthma due to bacterial allergy, I would like to report a very severe reaction to penicillin by an asthmatic patient.

The patient received treatments of an hour each for three successive days during one week and this was repeated again the next week. Penicillin, 40,000 units per cubic centimeter, was used and the aerosol technic was employed. Following the third treatment in the second week the patient, who had been suffering from asthma for fifteen years, went into status asthmaticus, which was very difficult to control. Nothing like this had occurred to this patient before. The attack was much worse than any which he had ever experienced.

It would seem important that controlled research should be undertaken on methods to avoid such reactions in asthmatic patients.

FRANKLIN E. BISSELL, M.D., Los Angeles.

POLIOMYELITIS VIRUS IN SEWAGE

To the Editor:—In the editorial comment on poliomyelitis virus in sewage (THE JOURNAL, September 7) the statement is made that "Kling's theory was presumably based on experimental or statistical errors." Kling's work was done on poliomyelitis organisms occurring in Stockholm sewage. The American investigators used American sewage and a mixture of laboratory strains of the organisms and did not obtain the same results as Kling. Is it fair to conclude therefore that Kling's theory was based on errors, either experimental or statistical, considering the possible differences in the sewage and the strains of the organisms? Would not the penultimate sentence have been a more scientific as well as a more courteous conclusion?

JOSEPHINE EVARTS, M.D., Kent, Conn.

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D.D.N.J. and foods, F.N.J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment.]

Adolorine.—John I. Wean, Eustis, Fla. Shipped Oct. 15, 1942. Composition: essentially oils of mustard and thyme, and a low-boiling petroleum oil. Misbranded because label falsely represented it as an effective remedy for sore muscles and joints from strain or overwork, for sprains, bruises, itching and nasal irritations. Further misbranded because label did not bear common or usual name of each active ingredient, since the composition was given in Latin rather than in English.—[*D. D. N. J., F. D. C. 994; November 1944.*]

Booth's Balm.—Booth's Hyomei Company, Ithaca, N. Y. Shipped April 16, 1942, by Dobson & Company, Nashville, Tenn., and Rutherfordton, N. C. Composition: plant extractives, particularly chlorophyll, as well as a cresol-like substance and a trace of eucalyptol, in a base of petrolatum and fatty material. Misbranded because label falsely represented product as effective in preventing or curing dandruff, pimples, blackheads, eczema and itching skin, besides benefiting bronchial catarrh, head colds, spasmodic croup, aching feet, tender breasts and sore nipples. —[*D. D. N. J., F. D. C. 1011; March 1945.*]

B. P. Stomach and Intestinal Corrective.—Burwell & Dunn Company, Charlotte, N. C. Shipped April 16, 1942, by Dobson & Company, Nashville, Tenn., and Rutherfordton, N. C. Composition: essentially bismuth subsalicylate, sugar and water, with a small amount of volatile oils, including peppermint. Misbranded because label falsely represented product to be efficacious for stomach fermentation, vomiting, diarrhea, cholera morbus and some other disorders in children and adults.—[*D. D. N. J., F. D. C. 1011; March 1945.*]

Chu-man-ie's Regular "Triple XXX" Herb and Iron Mensal Medicine.—Charles Roehm, trading as Chumanie Medicine Company, New Richmond, Ohio, and Detroit. Shipped Jan. 12, 1942. Composition: tablets containing ferrous sulfate and plant material, including aloe. Misbranded because labeling falsely represented product to be efficacious for amenorrhea, oligomenorrhea and dysmenorrhea and failed to warn that the product, as a laxative, should not be used continuously.—[*D. D. N. J., F. D. C. 1007; March 1945.*]

Dr. Wolff's Pro-cys-kera Ointment.—Dr. George F. Wolff, Chicago. Shipped Sept. 3, 1942. Composition: essentially sulfur, salicylic acid, menthol, camphor and ichthammol, in a base of saponifiable fat, lecithin and cholesterin. Misbranded because label falsely represented that product would eradicate scalp disorders and nourish, strengthen and promote the growth of hair, penetrate the scalp and prevent infection.—[*D. D. N. J., F. D. C. 992; November 1944.*]

Ekzebrol.—E. Tosse and Company, Brooklyn. Shipped Oct. 23, 1942. Label declared: "Ekzebrol 10% Strontium Bromide in Sterile Saline Solution For Intravenous Injection." Misbranded because of false label representations regarding alleged virtues of strontium bromide and also concerning alleged effectiveness of Ekzebrol in skin diseases.—[*D. D. N. J., F. D. C. 995; November 1944.*]

Fem-Re-Ills.—Henry S. Wampole Company, Baltimore. Shipped April 16, 1942, by Dobson & Company, Nashville, Tenn., and Rutherfordton, N. C. Composition: pills chiefly containing ferrous sulfate, calcium carbonate, oil of savin, sugar, and plant extractives, including aloes, and small amounts of ergot alkaloids. Misbranded because labeling falsely represented that product would correct various menstrual disorders.—[*D. D. N. J., F. D. C. 1011; March 1945.*]

Fero-Tona.—Great Lakes Laboratories, Cleveland; Ber-Mel, Inc., Cleveland, distributors. Shipped May 25 and Nov. 6, 1942, and Jan. 2, 1943. Composition: essentially hexamethylenamine, potassium iodide, ferric chloride, laxative plant drugs and strychnine sulfate. Misbranded because, among other things, label lacked warning against taking a laxative continuously or when symptoms of appendicitis are present, administering a strychnine mixture to children or elderly persons, or one containing potassium iodide to those having goiter, except on advice of a physician. —[*D. D. N. J., F. D. C. 1003; March 1945.*]

Formula "U."—Universal Antiseptic & Research Laboratories, Inc., Bristol, Tenn. Shipped Sept. 5, 1942. Composition: essentially water, carbolic acid, sugars, thymol, sage, alum, borates and aromatic substances. Misbranded because labeling falsely represented product as an adequate treatment for major burns, varicose ulcers and infected gums.—[*D. D. N. J., F. D. C. 993; November 1944.*] Possibly this is a later name for a product of essentially the same composition but slightly different name, "Universal Formula," put out by the same concern and declared misbranded under *D. D. N. J. 46,* issued in May 1940. This was abstracted in THE JOURNAL Nov. 2, 1940, page 1567.

Irogen.—Guardian Health Products Company, Inc., Atlanta, Ga. Shipped April 16, 1942, by Dobson & Company, Nashville, Tenn., and Rutherfordton, N. C. Composition: essentially alcohol, an iron salt, malt, cinchona and nux vomica alkaloids, a manganese salt, wild cherry, emodin-bearing drugs, phosphorus compounds, a sodium salt, sugar and water. Misbranded because falsely represented in labeling as efficacious for enriching the blood, building strength, restoring impaired tissues, aiding digestion and restoring tone to the system.—[*D. D. N. J., F. D. C. 1011; March 1945.*]

Jew David's or Hebrew Plaster.—Comstock & Company, Rochester, N. Y. Shipped April 16, 1942, by Dobson & Company, Nashville, Tenn., and Rutherfordton, N. C. Composition: a brown, somewhat plastic mass resembling Burgundy pitch and having a turpentine odor. Misbranded because label falsely represented product as efficacious for treating local inflammation, scrofulous conditions, gout, inflammatory and chronic rheumatism, lung and liver disorders, stomach pains and spinal weaknesses.—[*D. D. N. J., F. D. C. 1011; March 1945.*]

Liver-Cure—Munyon's Homeopathic Home Remedies.—Henry S. Wampole Company, Baltimore. Shipped April 16, 1942, by Dobson & Company, Nashville, Tenn., and Rutherfordton, N. C. Composition: small sugar pellets with nothing else detected. Misbranded because labeling falsely represented that product would be helpful for all liver disorders, as well as biliousness, constipation, bilious and sick headache, and would relieve bad taste in the mouth, coated tongue, worn-out feeling, highly colored urine, soreness in the right side, dull spirits and restless nights.—[*D. D. N. J., F. D. C. 1011; March 1945.*]

Nelson's Antacid Powder.—Great Lakes Laboratories, Cleveland. Shipped May 25 and Nov. 6, 1942, and Jan. 2, 1943. Composition: essentially compounds of sodium, calcium and magnesium, including carbonate. Misbranded because label falsely represented that, among other things, product offered a rational and effective method of re-establishing the normal alkalinity of the body fluids without the danger of systemic disturbance, instantly neutralized all stomach acids, and gave prompt relief from acidity and gas pressure.—[*D. D. N. J., F. D. C. 1003; March 1945.*]

Rheumatic No. 3 Tablets.—Charles Killgore Company, Inc., Yonkers, N. Y. Shipped Sept. 8 and Dec. 1 and 4, 1941. Adulterated and misbranded because strength differed from and quality fell below what was represented, namely, that each tablet contained 7½ grains of sodium salicylate, whereas not more than 6.18 grains of this was found.—[*D. D. N. J., F. D. C. 1012; March 1945.*]

Sani-Caps.—Sani-Caps, Rock Island, Ill. Shipped Nov. 12, 1942. Composition: essentially glycerin and boric acid with small amounts of iodide and a silver compound. Misbranded because label falsely represented product as being efficacious for "female trouble," even in cases of long standing. Further misbranded because represented to prevent infection. Misbranded also because label did not give names of active ingredients or name and place of business of manufacturer, packer or distributor.—[*D. D. N. J., F. D. C. 987; November 1944.*]

Targosine.—Targosine Company, Monroe, N. C. Shipped April 16, 1942, by Dobson & Company, Nashville, Tenn., and Rutherfordton, N. C. Composition: essentially turpentine, kerosene, fatty material, a water-soluble gum and water, with a small amount of chloroform. Misbranded because falsely represented as efficacious for eczema, rheumatic pains, croup, tonsillitis, vaccination sores and some other disorders.—[*D. D. N. J., F. D. C. 1011; March 1945.*]

Thompson's Daily Vitamin and Mineral Ration.—William T. Thompson Company, Los Angeles. Shipped Oct. 12, 15 and 20, 1942. Composition according to label: vitamins A, B_1, B_6, C, D and G, niacin amide, pantothenic acid, biotin, calcium, phosphorus, iodine, iron and copper. Misbranded because falsely represented, among other things, to improve appetite and digestion, build nervous stability, prevent impaired eyesight due to vitamin deficiencies, build up the blood count, prevent dental cavities and bleeding gums, reduce colds, cut down fatigue, and do some other things.—[*D. D. N. J., F. D. C. 997; November 1944.*] Further misbranded under provisions of the law applicable to foods, as reported in *F. N. J. 5787.*

Triple-X Medicine.—Triple X Laboratories, Scotland Neck, N. C. Shipped April 16, 1942, by Dobson & Company, Nashville, Tenn., and Rutherfordton, N. C. Composition: copaiba and cubeb oils and a sugar solution, emulsified with a water-soluble gum. Misbranded because label falsely represented that product would prevent or cure acute and chronic discharges, and because label did not bear common or usual name of each active ingredient.—[*D. D. N. J., F. D. C. 1011; March 1945.*]

Viteen.—L. N. LeBold & Company, Rochester, N. Y. Shipped between Aug. 15 and Oct. 27, 1942. Composition: chiefly dried skimmed milk, with smaller amounts of egg yolk, sugar, cereal products, calcium and phosphorus compounds, and flavoring material. Misbranded because of label representations as to protein and mineral content and as to suitability as a weight reducer and a supplement to restricted and unbalanced diets.—[*D. D. N. J., F. D. C. 990; November 1944.*] Also misbranded under provisions of the law applicable to foods, as reported in *F. N. J. 5786.*

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Liability of Physician for Departing from Approved Methods.—The plaintiff sued for damages for injuries resulting from the alleged negligence of the defendant in the treatment of a fracture. From a judgment for the plaintiff, the defendant appealed to the Supreme Court of North Carolina.

The plaintiff fractured one of the bones in her right forearm and engaged the defendant physician to treat her. He set the bone and put the arm and wrist on a board splint. Later he removed the board splint and substituted a metal cast, at the same time massaging the plaintiff's arm and hand. The defendant subsequently visited the plaintiff once or twice a week, the plaintiff testifying:

> Each time he came he brought a tube or something and massaged my arm. He would take my arm out of the cast and massage it. He would not support the broken part of my arm while he was massaging it. . . . He held it with the fingers in one hand and rubbed my arm and hand with his other hand.

After about three months the plaintiff's hand was so drawn and bent that she could not use it, and the defendant took her to another physician who examined her arm and took an x-ray. He found the bone out of position and testified that the displacement could have occurred when the physician removed the arm from the splint. The plaintiff introduced expert evidence to the effect that the manner in which the defendant massaged the plaintiff's arm "was unusual" and not according to the general practice, and that "too frequent removal of a broken bone from the cast is bad practice . . ."

The Supreme Court said that a departure from approved methods in general use, if injurious to the patient, suffices to carry the case to the jury on the issue of negligence. On the basis of all the evidence the court was of the opinion that the removal of the cast once or twice a week and the massaging of the plaintiff's arm and hand without any support under the broken part was unusual and a departure from approved methods in general use. The jury was warranted, concluded the court, in finding that such conduct was injurious, so the judgment for the plaintiff was accordingly affirmed.—*Davis v. Wilmerding, 24 S. E. (2d) 337 (N. C., 1943).*

Privileged Communications: Physician's Report to Insurer.—Plaintiff obtained an award for an industrial injury, the award being against the defendant insurance company. Subsequently the insurance carrier filed a motion to reopen the case and discontinue payments on the award. Attached to this motion was a physician's report as required by the workmen's compensation act. On the theory that this report was libelous, the plaintiff filed suit for damages against the insurance company and obtained judgment in the trial court, from which judgment the defendant appealed to the Supreme Court of Oklahoma.

The physician's report, in the form of a letter addressed to the manager for the insurance carrier, stated among other things that in his opinion the plaintiff exaggerated his condition and appeared to be in good health, suffering from no disability and able to do light work. The report then contained this paragraph:

> This patient has had a positive Wasserman test on two previous occasions, a positive Wasserman test was obtained during my treatment. He was given several shots of Mapharsen and seemed to improve, but he absolutely refused further Leutic treatment because it made him sick. He flatly refused to have a spinal puncture done to determine his Wasserman reaction and colloidal curves for Lues.

The plaintiff contended that the statement was libelous and was not relevant and pertinent to the issue involved in the proceeding to discontinue compensation, whereas the defendant contended that the statement was absolutely privileged.

The Oklahoma statute (12 O. S. 1941 section 1443) provides:

> A privileged publication or communication is one made: First. In any legislative or judicial proceeding or any other proceeding authorized by law; . . . No publication which, under this section, would be privileged, shall be punishable as libel.

Furthermore, rule 17 of the state industrial commission provides:

> The Commission will not consider nor set for hearing any motion to discontinue payment of compensation ordered . . . unless such motion to discontinue compensation sets up sufficient grounds supported by a physician's report.

It is clear, said the Supreme Court, that a proceeding before the state industrial commission is a "proceeding authorized by law" within the purview of section 1443. It is also clear that it is proper and necessary to file a physician's report with a motion to discontinue compensation under rule 17. Bearing in mind the foregoing rules, we are of the opinion, and hold, said the court, that the statement here complained of was pertinent to the question raised by the motion to discontinue compensation. The motion contained the allegation that the claimant "is able to return to ordinary manual labor and is entitled to no further compensation" by reason of the injury. The physician's report tended to sustain such allegation. If the disability was due entirely to syphilis, the court continued, the insurance carrier was not liable for further compensation. And, since the matter complained of was filed as a part of the pleading in the case, the question as to whether the matter was pertinent or relevant was one for the court to determine as a matter of law and not one to be submitted to the jury. The court accordingly concluded that the matter complained of was absolutely privileged, that a question of its being false or made with malice was immaterial, and the judgment in favor of the plaintiff be reversed.—*Pacific Employers Insurance Company v. Adams, 168 P. (2d) 105 (Okla., 1946).*

Medical Motion Pictures

FILM REVIEW

Hemostasis with Oxidized Cellulose (Absorbable Gauze and Cotton). Prepared in 1946 by Virginia Kneeland Frantz, M.D. 16 mm., color, silent, 850 feet (one reel). Showing time, thirty-five minutes. Investigation carried out at Columbia-Presbyterian Medical Center under OSRD Contract. Procurable on loan from the author at Department of Surgery, Columbia University College of Physicians and Surgeons, 630 West 168th Street, New York 32.

This film presents an experimental and clinical study of the new hemostatic agent oxidized cellulose. The color photography is excellent. The film begins with the presentation of the chemistry and physical properties of oxidized cellulose as well as its biologic properties when the oxidized cellulose comes in contact with blood. Tests of the absorptive properties of the oxidized cellulose are demonstrated in experiments on rats, and the hemostatic properties are demonstrated in experimental operations on dogs, in which incisions are made in the kidney and the spleen. The film then presents clinical data on the use of oxidized cellulose in operations for brain tumor, in which oxidized cotton is used to control bleeding from the dura, and oxidized gauze is used to control bleeding from the bone flap.

In another clinical case in which a biopsy of the kidney is performed, the use of the oxidized gauze is demonstrated. In a suprapubic prostatectomy the oxidized gauze is used for controlling the bleeding from the prostatic bed. In a case of chronic varicose ulcer in which deep incision is made into the scar tissue about the ulcer, the oxidized gauze is used as an aid in controlling bleeding. This particular case illustrates one interesting feature of the oxidized cellulose in that it can be subsequently peeled away from the raw surface after three days without any evidence of adherence of the gauze to the raw surface of the wound and thus without causing any further bleeding.

This film is of value to the surgeon to give a better understanding of the properties of oxidized cellulose and the technic of application to obtain hemostasis. It would be a suitable film for surgeons and for resident staff personnel.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Gum Chewing and Gastric Acidity.—Twelve healthy persons without apparent gastric disturbances who had served as subjects for several gastric analyses in a previous investigation were used for this study. After the standard test meal of crackers and water each subject chewed 2 Gm. of a chewing gum (composed of chicle flavored with oil of peppermint) for a period of five minutes. It was found that the chewing of gum depressed the gastric acidity of two thirds of the subjects during the period of an hour. Both the total and the free acidity were depressed in five sixths of the subjects for the first half hour. The maximum total acidity was less in 11 of the 12 subjects when gum was chewed. The time required to reach this maximum did not vary materially from the time required when no gum was chewed.

Continuous Drip Treatment for Chronic Ulcerative Colitis.—Nasio treats patients with ulcerative colitis by administering a colloidal preparation similar in mechanical properties to the normal secretion of the intestinal mucosa. He attaches a latex tube to a continuous drip apparatus and introduces it through the nose as far as the cardia. A 1:2 or 1:3 suspension of kaolin in alumina gel with liquid petrolatum 500 Gm., to which has been added bismuth subgallate 50 Gm., is placed in the drip apparatus. Seven hundred Gm. of the mixture usually is administered in twenty-four hours, although more may be given with safety. Sulfaguanidine or succinylsulfathiazole and any antispasmodic remedy, as 10 per cent paregoric, also may be added if desired. The drip is permitted to flow at the rate of 10 drops per minute the first day, later increased to 20 drops per minute as tolerated by the patient. The drip is discontinued for half an hour before and after breakfast and the midafternoon feeding, and for one hour before and two hours after lunch and dinner. During these intervals the patient may be permitted out of bed. Treatment is continued for periods of fifteen days, with rest intervals of not less than a month, and is repeated as necessary. Six cases of serious chronic ulcerative colitis are described, in which symptomatic relief occurred in eighteen to forty-eight hours after drip treatment was begun, with progressive clinical, roentgenographic and rectosigmoidoscopic evidence of improvement. In 2 cases a remission necessitated further drip treatment.

Aspiration of Stomach Contents into Lungs During Obstetric Anesthesia.—Mendelson says that there have been 66 instances of aspiration of stomach contents into the lungs in 44,016 pregnancies, an incidence of 0.15 per cent. Two entirely different syndromes may follow aspiration. Aspiration of solid food usually produces laryngeal or bronchial obstruction. Complete obstruction produces suffocation. Incomplete obstruction produces massive atelectasis with cyanosis, tachycardia, dyspnea, mediastinal shift and signs of consolidation over the collapsed area. Obstruction should be promptly relieved either indirectly by external stimulation, with encouragement of coughing, or directly with the aid of suction and endoscopic removal. Aspiration of liquid material produces an asthma-like syndrome. There are cyanosis, tachycardia and dyspnea but no mediastinal shift or massive atelectasis. Wheezes, rales and ronchi are heard. X-rays reveal irregular, soft, mottled densities without mediastinal shift. The picture has been misinterpreted as bronchopneumonia, tuberculosis, fungous infection and even metastasis. Progressive cardiac embarrassment and pulmonary edema may supervene. Animal experiments indicate that hydrochloric acid is responsible for these changes. Treatment should be directed against the bronchiolar spasm and cardiac embarrassment. Oxygen, atropine, epinephrine and aminophylline will accomplish these objectives. Should cardiac failure develop, rapid intravenous digitalization is indicated. The circulatory burden may be relieved by the application of tourniquets to the extremities to produce the effect of a *bloodless phlebotomy*. Aspiration of stomach contents into the lungs may be avoided by withholding oral feeding during labor, by wider use of local anesthesia when feasible, by alkalization of the stomach contents and emptying the stomach prior to the administration of a general anesthetic, by competent administration of general anesthesia and by adequate delivery room equipment, including transparent anesthetic masks, tiltable delivery table, suction, laryngoscope and bronchoscope.

Heart Disease in Pregnancy.—Stromme and Kuder report 720 cases of heart disease, which represent 3.02 per cent of the 23,858 pregnancies cared for between 1937 and 1944. They stress the importance of hospitalization prior to labor. Special care must be given to these women in labor. The second stage must be shortened by operative means, particularly in the woman with severe cardiac defects. The authors have noted a trend from cesarean section to forceps deliveries, a greater use of local anesthesia and liberalization in interruption of pregnancies in bad risk cases. These factors explain a lowering of the maternal mortality among cardiac patients from 14.18 to 12.64 per thousand pregnancies. A further lowering of this figure is possible through better cooperation in early registration and through improvement in selection of patients for therapeutic abortion, earlier interruption and sterilization. Infantile mortality is essentially unaffected by maternal heart disease.

Boiled Cartilage Implants.—Firestone uses cartilage from subjects who have been prepared for burial. The cartilage is vigorously boiled for twenty minutes and then placed in a 50 per cent solution of alcohol and kept there at room temperature until the need for it arises. At that time pieces of desirable size are removed from the alcohol, washed in tap water, wrapped in gauze and boiled vigorously for twenty minutes in the sterilizer, together with the instruments. The boiling removes all trace of the preservative. They are then brought to the operating room, shaped to fill the particular contour deformity, perforated and implanted in the routine manner. Cartilage from Negro and Japanese subjects were implanted, together with cartilage from Caucasians, into the same Caucasian recipients. Results have been uniformly favorable. Heterocartilage (bovine) is transplantable to man and holds promise of becoming the implant of choice, because of its coefficient of increased reaction in locations where subcutaneous soft tissues require elevation.

Late Repair of Tendons.—Webster points out that primary suture of flexor tendons in the fingers still results in failure at the hands of all but a few experts, and most of these cases result in disabilities which require late plastic repair. If infection has occurred, if foreign bodies have remained in the wound or if multiple surgical procedures have been performed, late tendon repair offers only a fair chance for recovery of function. If fingers have been ruthlessly opened, cutting across flexion creases at right angles and destroying the "pulley" mechanism in the fingers, little hope can be given for restoration of function. Some of these cases can be improved by excision of all volar scar and replacement with a pedicle flap of skin and fat. A hand with flexible joints, intact nerves and good circulation presents the ideal situation for late tendon repair. A final evaluation of results should be deferred for a year to eighteen months. Tendons, like bones, aline their structure in the direction of the stress which is put on them, and often a finger which flexes poorly at three months will be improved at six months and with active exercise it may be moving well six months to a year later. Premature reexploration of a finger that has been operated on may forfeit all chance of final improvement. The author stresses the importance of knowledge of anatomy, of a bloodless field, of carefully planned incisions and of closure of wounds without buried sutures. The cooperation of the patient must be excellent. Good results are frequent, but excellent results are rare.

Splenectomy in Familial Hemolytic Jaundice.—Eisendorf and Broun report a case of congenital hemolytic icterus which was cured by splenectomy. The following unusual features were presented: the fragility of the erythrocytes was normal; microspherulosis was minimal; the liver damage was improved by splenectomy and an unusual postoperative hemolytic crisis resulted with a drop in the erythrocyte count to two and a half million.

Cellophane in Treatment of Wounds.—Chistyakov used cellophane gauze dressing in the treatment of superficial and deep gunshot wounds in their later stages and in open and closed operative wounds. Cellophane is applied directly over the affected part and will not absorb any secretions. The space between the cellophane layer and the wound gradually fills with secretions, which escape at the wound edges, where they are absorbed by the superimposed layer of gauze. The exudate at the bottom and around the edges of the wound underneath the cellophane prevents drying. The retained moisture is highly desirable for normal healing. The protective covering of cellophane keeps the wound at body temperature, which is essential for tissue regeneration. Cellophane does not stick to the surface of the wound and can be easily removed without disturbing normal healing. Subsequent dressings can be performed with little pain or discomfort to the patient. At evacuation points a wound can be examined and observed under the cellophane after the covering gauze dressing has been removed. Cellophane dressings are convenient in skin grafting operations, as they protect the wound from drying and do not disturb the grafted epidermis. No delay in healing nor any complications were observed which could be attributed solely to the cellophane gauze dressings.

Vaccination Against Typhus.—Krontovskaya obtained large quantities of Rickettsia prowazeki from the lungs of white mice by infecting the animals with material obtained from the tunica vaginalis of diseased guinea pigs. The material was instilled intranasally into the mice. For continued passage and for the preparation of vaccine, the lungs of the mice were removed aseptically. An emulsion of the lung tissue containing a great number of extracellular Rickettsia prowazeki was made, isotonic solution of sodium chloride containing 0.2 per cent formaldehyde added and fractional centrifugation done. A suspension of clean, washed-out Rickettsia prowazeki was obtained and diluted according to a standard with isotonic solution of sodium chloride containing 0.2 per cent of formaldehyde. Experiments on guinea pigs and serologic studies on human subjects were made which suggest that the vaccine is harmless. It causes only mild and general reactions and increases specific antibodies in the serums of vaccinated persons. From statistical material and observation on 200,000 persons among medical personnel and populations in the formerly occupied territories, it appears that the type of typhus developed by vaccinated persons was atypical and abortive, preceded by a long incubation period of twenty-three days, with moderate fever lasting six to seven days. Patients recovered rapidly. The changes following vaccination suggest that the vaccine has a specific antigenic value.

Results of Pneumolysis.—Marcus and Pinner studied the records of 302 consecutive patients who were subjected to thoracoscopy during the course of treatment for pulmonary tuberculosis. Thirteen of the 302 patients had bilateral simultaneous pneumothorax and thoracoscopy was performed on each side, thus bringing the total pneumothoraces under consideration up to 315. Complete pneumolysis was performed 88 times, partial pneumolysis was performed 142 times, insignificant pneumolysis was performed 31 times and thoracoscopy only was performed 140 times, so that the total number of operations was 401. As a result of 315 pneumothoraces 126 patients (40 per cent) were benefited by the operative procedure directly, while 125 (39.7 per cent) did well during the later course of observation, some by the institution of other treatment. All but 42 patients (13.9 per cent) have been observed for from two to more than six years. Serious complications were generally due to the development of postoperative empyema, the incidence of which was 4 per cent in 401 operations. Ten of 16 patients who developed empyema died, an incidence of 3.2 per cent for the total number of 302 patients. The authors feel that a conservative attitude in approaching adhesions is justified.

Vaccination with Vole Bacillus.—Birkhaug compared the protective value of the multiple puncture and intravenous vaccination of guinea pigs with the vole bacillus. Ninety days after the vaccination with the vole bacilli all animals in the multiple puncture, intracutaneous and control groups were inoculated subcutaneously with 0.00001 mg. of human virulent tubercle bacilli. Quantitative assessment of tuberculous hyperplasia of the various lymph nodes and viscera revealed that the vaccination with the vole bacillus offers a relatively high protection against a test infection with virulent human tubercle bacilli and that the multiple puncture method yields results which lie slightly ahead of those observed with the intracutaneous method. In a small series of human experiments the vole bacillus vaccine and the BCG vaccine were applied with the multiple puncture method to 12 women between the ages of 17 and 44 and to 6 men between the ages of 17 and 41. Multiple puncture vaccination with the vole bacillus (Wells) produced more permanent vaccination marks and stronger tuberculin reactions than a similar vaccination with BCG, suggesting a lesser margin of safety for the vole bacillus as a vaccine for use on man.

Mango Dermatitis and Poison Ivy Hypersensitivity.—Keil and his associates report a case of mango dermatitis. This type of dermatitis is likely to be encountered with increasing frequency owing to the increasing consumption of the fruit and to the close immunologic relation to hypersensitiveness to poison ivy and related plants. Experimental studies on 39 subjects showed that the irritant is the stem sap which often contaminates the external surface of the peel. The majority of the 39 subjects had had no prior contact with the mango fruit. Based on the responses to 3-n-pentadecyl catechol, which was the standard method of detecting hypersensitiveness to poison ivy, the subjects could be classified in two categories: 1. A group of 14 persons who were not sensitive to poison ivy, all of whom showed negative responses to various portions of mango fruit, including the stem sap. 2. A group comprising 25 persons sensitive to poison ivy, 9 of whom were seen in a clinical attack of poison ivy dermatitis. In this group cross reactions were obtained from stem sap in 14 of 21 persons and from the internal surface of the peel in 6 of 24 persons. When comparisons were made on a quantitative basis it was found that the specimen of mango stem sap was about equivalent in its cutaneous effects to 0.1 per cent 3-n-pentadecyl catechol. All subjects who were observed in a clinical attack of poison ivy dermatitis showed positive patch tests to the stem sap and some of them to the internal surface of the peel. The possibility that persons sensitive to poison ivy are more easily sensitized to the mango plant was illustrated by 2 persons in the control group.

Benadryl in Erythema Exudativum Multiforme.—Pinkus used benadryl in 2 cases of idiopathic erythema multiforme in which high doses of sodium salicylate had produced only temporary alleviation. The cutaneous and general symptoms were relieved in both cases with surprising promptness by comparatively small doses of benadryl. Two later recurrences in 1 of the cases also responded quickly to the same therapy. One case of toxic erythema following vaccination and 1 of erythematous drug eruption subsided with similar rapidity.

Electric Shock Treatment of Elderly Patients.—Feldman and his associates present observations on 53 patients over 65 years of age who were subjected to shock treatment at the Albany Hospital. The significance of an impaired cardiovascular system in the patient with serious mental illness must be evaluated in terms of what the future holds for the patient with and without treatment. When a diagnosis other than senile dementia can be made in a patient over 65, especially that of depressive, manic or paranoid psychosis, electric shock treatment should be considered. The only contraindications should be extreme defects in the physical state, particularly in the cardiovascular system. The value of the treatment is seen in the high proportion of patients returned to their homes as either recovered or much improved. The figures for improvement compare favorably with those obtained in the treatment of younger patients with similar conditions, especially the depressions. The paranoid states responded least well, with 3 failures among 6 patients. The psychoneuroses, while not showing complete recovery, were greatly improved in the majority of cases.

Changes in Lens of Embryo After Rubella.—Microscopic examination of the eye of a 7 to 8 week embryo with a history of rubella during the sixth week of pregnancy revealed to Cordes and Barber definite changes in the lens. The lens showed retardation of development and differentiation, while the posterior segment of the eye seemed normal. The absence of the protection of the lids and of Descemet's and Bowman's membranes during the first three months of pregnancy may permit the toxic agent in the amniotic fluid to act directly on the lens during this time. The presence of these barriers after the third month may explain the absence of initial changes in the lens after that time. The study of more specimens is necessary in order to evaluate the changes reported here.

Vein Interruption in Thromboembolism.—Goldman and Johnson review observations in 71 cases of thromboembolism encountered in the University of California service at the San Francisco City and County Hospital during a period of twenty-six months between 1943 and 1945. Ligation of the iliofemoral venous system was resorted to in 25 cases, 30 were treated by other means than ligation, and 16 were not diagnosed until necropsy and were not treated. The authors stress that ligation or interruption of the iliofemoral veins is a life saving procedure in patients who have had pulmonary embolism. It should be carried out early in order to prevent extension of the thrombus into the pelvic veins with resultant phlegmasia alba dolens and persistent edema. Vein ligation should not be postponed until the patient has had multiple pulmonary infarctions. Bilateral rather than unilateral ligation is preferable because the pathologic process may be symmetrical even though there are no clinical findings in one extremity. In patients with adherent vein thrombosis (thrombophlebitis) ligation should be done proximal to the thrombus. Edema is no more severe when ligation is done than when it is not and is usually lessened if ligation is carried out early.

Pathologic Effects of Instantaneous Dose of Radiation.—Warren presents studies on the atomic bomb effects at Nagasaki and Hiroshima, which were carried on under the direction of the Naval Medical Research Institute and the Naval Technical Mission to Japan. Particular attention was given to the injuries due to radiation, although as the patients were studied it became apparent that the same one might be suffering from blast effect, thermal injury and radiation injury simultaneously. Two stages of radiation injury are differentiated, the immediate and the delayed. As the result of the extreme disorganization no adequate material exists to determine the exact nature of immediate effects, but Warren assumes that there is little morphologic evidence other than leukopenia and loss of adrenal lipoid. Material on the delayed effects was extensive. Over 800 patients were hospitalized by the author's group and about 13,000 were surveyed. Most leukopenic deaths occurred during the first three weeks subsequent to the bombing. From three to five weeks after the bombing a considerable number of hemorrhagic deaths occurred, associated with the thrombocytopenia induced by radiation damage to the megakaryocytes of the bone marrow. Those with serious bone marrow damage who weathered the first few weeks showed later anemic manifestations, with red blood cell counts in some instances dropping to 1 million or below. The gonadal effect was much more prominent in the testis than in the ovary.

Hepatic Tests in Chronic Hepatitis Without Jaundice.—In the course of investigations on infectious hepatitis in human volunteers, Neefe observed 4 cases of chronic hepatitis without jaundice. The chronic form of the disease followed an attack of acute infectious hepatitis with jaundice, although in case 2 the icterus associated with the acute attack was transient and subclinical. In cases 1, 2 and 3 the acute hepatitis had been induced by the oral administration of a feces preparation known to contain the causative agent of infectious (epidemic) hepatitis. In the fourth case, observed in a hospital, the infectious hepatitis had been acquired under natural circumstances. In all these cases the duration of the illness exceeded seven months and a diagnosis of chronic hepatitis without jaundice was made on the basis of the history, the clinical manifestations, laboratory evidence and, in cases 1 and 2, on the microscopic findings in liver biopsy specimens obtained nine and six months respectively after the onset of acute hepatitis. The course of the disease after the seventh month was one of progressive improvement, and in 2 cases complete recovery appears to have been achieved. In the later stages of the disease, it was found that the commonly used hepatic tests failed to reveal hepatic disturbance, although incapacitating symptoms continued and liver biopsies showed persistent hepatitis.

Nocturnal Gastric Secretion.—Sandweiss and his associates studied nocturnal gastric secretion in 38 normal subjects and 29 patients with duodenal ulcer. They arrive at the conclusion that following a fairly well balanced meal at 6 p. m. a normal person secretes acid gastric juice during the night. An average of 446 cc. of gastric juice was obtained by continuous suction from 12 midnight to 7 a. m. (minimum 190 cc., maximum 800 cc.). There is no statistically significant difference in the volume and total output of acid of nocturnal gastric secretion of normal subjects and patients with uncomplicated duodenal ulcer when determined by continuous aspiration. The greater volume of gastric juice observed when intermittent single aspirations are made from patients with uncomplicated duodenal ulcer is not due to gastric hypersecretion. The authors emphasize the need for additional studies on nocturnal gastric secretion on both normal subjects and ulcer patients by the continuous aspiration method.

Traumatic Effects of Positive Intratracheal Pressures. H. Tatum and A. M. Ginzler.—p. 799.

Starvation in Young Men.—Davidson and his associates present observations on 171 men suffering from a severe degree of starvation. The men were German prisoners who were seen between two and three months after imprisonment; during this interval the value of the food eaten varied between 650 and 850 calories daily. Food eaten before the time of capture may not have been entirely adequate. Extreme wasting was evident and was usually associated with lethargy, a stooped posture, weakness and often syncope. Comparison of actual weight with data given in standard height and weight tables showed that all the men were under the standard of weight, the average being 13 Kg. below the standard. Joint pains were common, particularly in the knees. Diarrhea was a frequent complaint. A generalized pigmentation was observed. There was a high incidence of follicular hyperkeratosis, 4 instances of circumcorneal injection, 3 instances of color change in the tongue and 8 instances of papillary atrophy of the tongue. Eye signs suggesting vitamin A deficiency were not observed. A condition resembling acrocyanosis was observed in the distal extremities of many of these men and was often associated with paresthesias. Edema, probably of nutritional origin, was observed in 24 per cent of these men. Hypoproteinemia was common but was not present in a significant number of the men with edema. Anemia was not severe.

Hematologic Survey of Repatriated American Military Personnel.—Cartwright and Wintrobe made hematologic studies on 75 repatriated American prisoners of war selected from a series of 3,000. These men had been on a grossly inadequate diet consisting mainly of rice for an average of 40.1 months. The average weight loss was 37 pounds (17 Kg.). A history of nutritional deficiency as characterized by cheilosis, glossitis, stomatitis, dermatitis and diarrhea was obtained in from 50 to 70 per cent. A history suggesting wet beriberi was obtained in 77 per cent and a history of dry beriberi in about 50 per cent. Among the 75 patients studied in detail, the anemia was macrocytic in 73 per cent, normocytic in 23 per cent and microcytic in 4 per cent. Thrombocytopenia was present in 1 patient who had a mild elevation of the icterus index. In the remaining cases the icterus index was normal. Mild reticulocytosis and leukocytosis, were frequently encountered. Blood films showed numerous macrocytes, anisocytosis, polychromatophilia and an occasional nucleated red blood cell. In approximately half of the men studied, normal serum iron and copper values were found. The other half were characterized by hypoferremia and hypercupremia. It is suggested that most of the men examined probably presented the recovery phase of severe nutritional macrocytic anemia. The 3 cases of microcytic anemia were most likely due to blood loss.

Schistosomiasis Japonica in American Soldiers.—Following the invasion of Leyte, cases of schistosomiasis japonica began to appear among army personnel. Mason and his associates describe investigations on 481 patients. Several weeks after exposure the patients developed chills, sweats, generalized malaise, lethargy, headache, anorexia, mild diarrhea and abdominal pain, with weight loss. Urticaria and jaundice were observed in some cases. Examination revealed a slightly enlarged and tender liver and occasionally an enlarged spleen. Leukocytosis with eosinophilia was usual. Four to nine months after their acute illness, patients were evacuated to this country. On arrival they did not appear ill. The only abnormalities were recurrent cramps and tenderness in the upper abdomen. A slightly enlarged liver was felt in 10 per cent of the patients. During observation for three months or more the patients tended to improve. On discharge almost all were free from symptoms. Eggs were found either overseas or here in 80 per cent of these patients. In the remainder the clinical history was sufficiently characteristic to warrant little doubt of the diagnosis. A persistent eosinophilia was suggestive but not diagnostic of continued activity of the disease. On the basis of comparable series, treatment with antimony and potassium tartrate was found to be much more effective than treatment with fuadin. Significant toxic reactions with antimony and potassium tartrate were rare. It is urged that stool examinations be done repeatedly and by multiple methods on men who have been exposed to this disease so that treatment may be instituted if ova are found.

Tonic Effects of Insulin in Acute Alcoholism.—Vassaf and Hall report observations on 43 patients with uncomplicated alcoholic intoxication who were treated with small doses of insulin but who were not given the usual liberal amounts of dextrose. During the gradual withdrawal of alcohol they were given 10 units of insulin two or three times daily before meals. The insulin-treated cases as compared with the control group showed the following clinical differences: The average speed of the withdrawal period was twice as great. Three times as many patients neither required nor demanded whisky after admission. Subjective comfort during the withdrawal period was increased. Supplementary sedation was greatly reduced, in some cases to zero. The weight gain was increased by threefold, both during the first week of hospitalization and subsequently. Insulin reactions were rare and mild, being readily controlled by oral sugar. The coverage of clinically effective doses of insulin by dextrose as such is apparently not a necessity.

Bronchiectasis of Left Lower Lobe.—p. 232.

Scleredema.—Vallee says that the condition was first described by Buschke in 1900 and that since then 99 cases have appeared in the literature. To this number he adds 4, all of which were observed at Mount Sinai Hospital within the last six years. The disease is characterized by firm, nonpitting edema, affecting usually the face, neck, scalp, conjunctivas, thorax, occasionally the arms and more rarely the legs, sparing the hands and feet. Pleural effusions, pericardial effusions and hydrarthroses also occur. The pericardial effusions may be localized. The electrocardiogram shows low voltage of the QRS complexes. Young people are affected more frequently than those in the older age groups. Women are affected twice as often as men. The treatment was unsatisfactory. Vallee's therapeutic trials included desiccated thyroid, dihydrotachysterol and anterior pituitary extract. These agents did not contribute greatly to recovery.

Unusual Aspects in Epidemic of Anterior Poliomyelitis—During March and April 1945 a southern army post experienced a short outbreak of anterior poliomyelitis. Within a period of twenty-five days 18 patients with poliomyelitis were admitted to the hospital. All the cases occurred in soldiers; all but 3 were between 18 and 21 years old. The patients showed some unusual findings. There were 10 with bulbar involvement. There were 3 deaths, all of patients with bulbar involvement and all caused by failure of the respiratory center. A large percentage of the patients failed to show the cellular response usually seen in the spinal fluid in poliomyelitis. The albuminocytologic disassociation described in the Guillain-Barré syndrome was found in 3 of the 18 cases in this series.

Pulmonary Torulosis.—Hamilton and Tyler report 1 case of Torula infection involving both the central nervous system and lungs in a woman aged 24. Mild symptoms such as pleuritic pain and mild cough called attention to the pulmonary infection. A round opacity having the characteristics of an inflammatory lesion in the upper portion of the left lower lobe was demonstrated on roentgenologic examination. Symptoms referable to the central nervous system were manifested four months after the occurrence of the lung lesion. Spinal fluid cultures revealed a budding yeast organism typical of Torula histolytica. Saturated solution of potassium iodide 3 minims (0.2 cc.) three times daily was given, and the dosage was eventually increased to 15 minims (1 cc.) three times daily. One week after institution of this treatment a chest roentgenogram showed partial clearing of the lung lesion, but no clinical improvement occurred. Sulfathiazole, acriflavine and 110,000 units of penicillin proved ineffective. The neurologic symptoms increased and death ensued seven months after the onset of the first pulmonary symptoms. The possibility of pulmonary torulosis should be borne in mind when there is a persistent asymptomatic or relative asymptomatic parenchymal lesion which has inflammatory characteristics and which is resistant to diagnosis by ordinary laboratory procedures, especially if the patient is showing no evidence of a malignant neoplasm.

The changes occurring in the lungs, as reported by others, may assume various appearances and are not characteristic of the disease but usually suggest the possibility of tuberculosis. The lung lesion may precede by months the onset of central nervous system symptoms.

Penicillin in Acute Osteomyelitis.—Hamilton and Boyd have used penicillin in the treatment of acute and chronic osteomyelitis for the past eighteen months. Histories of 11 cases are reported. The earlier the penicillin therapy is instituted, the quicker will be the response and the better the end result. There may be an occasional infection with a penicillin resistant staphylococcus. In cases not responding to penicillin one of the sulfonamides is prescribed and vice versa. There may also be cases in which the two drugs may be used simultaneously to greater advantage. In a patient with a pocket of pus infected with a susceptible pathogen, even though the action of penicillin is not inhibited by organic matter as are the sulfonamides, it may not, for physical reasons, arrest the growth of staphylococci in the abscess. Such accumulations of pus should be drained, especially if response to penicillin is delayed. Penicillin should be given for at least five days after the temperature has returned to normal, and the total amount of penicillin for patients with acute osteomyelitis should be at least 1 million units. The economic factor in reducing the length of hospitalization as the result of penicillin therapy is astounding when compared with former methods.

Penicillin in Coccidioidomycosis.—Arnold and Levy report a case in which the course was typical of acute coccidioidomycosis followed by the disseminated or granulomatous stage. A Negro aged 32, who was a waiter on a train that traveled from Texas to California through Arizona, complained of coughing, cold, low grade fever, chills, night sweats, pain in the left shoulder, substernal pains and hemoptysis. The first x-ray diagnosis was tumor of the left hilus, probably a bronchogenic carcinoma; but on bronchoscopy no tumor was found. Later a diagnosis of tuberculosis of the glandular type was made and then a questionable diagnosis of Hodgkin's disease, for which x-ray therapy was given. During a final hospitalization a chronic meningitis was diagnosed and large doses of penicillin were given intramuscularly and intraspinally, but the patient died.

Another Lactobacillus Casei Factor.—A new Lactobacillus casei factor has been described by Hutchings and his associates. The compound was obtained from a fermentation residue and was almost as active as the liver L. casei factor when assayed with L. casei, but only 6 per cent as active when assayed with Streptococcus fecalis R. When a small quantity of the natural fermentation L. casei factor became available, Spies tested it on a man aged 65 with pernicious anemia in relapse. He had responded twice to reticulogen but relapsed when he did not wish to continue the injections. This time on his fourth hospital day, a 3 mg. injection of natural fermentation L. casei factor was given intramuscularly and was repeated daily for eleven days. On the fifth day the reticulocytes had risen from 1 per cent to 2.6 per cent and on the tenth day reached a peak of 5.4 per cent. After that they subsided slowly, but by the sixteenth day the red blood cells had risen from 1.89 to 2.4 millions and the hemoglobin had likewise increased. There was also great subjective improvement. The ingestion of the material did not cause any untoward symptoms.

Acute Secondary Parotitis.—During the past nine years Altemeier has seen 49 patients with acute secondary parotitis. The ages of these patients varied between 7 and 84. The infection involved the right side in 25 instances, the left in 19 and both in 4. All but two of the infections occurred in patients debilitated by some primary disease or injury. One of the causal factors was poor oral hygiene. Dehydration, mouth breathing, suppression of salivary secretion and the existence of dental caries favored the development of an ascending infection along Stensen's duct. A sharp elevation of body temperature, pulse rate and white blood cell count usually occurred. Treatment consisted in the administration of 120 to 250 minims of Lugol's solution per day at the earliest opportunity until improvement occurred. Thereafter the daily dose was progressively reduced. The greater part was given by mouth whenever possible, and supplemental amounts were given by hypodermoclysis, intravenous infusion or proctoclysis. Treatment for the primary disease was continued, and supportive therapy included the use of hot compresses. Early and adequate treatment with massive doses of Lugol's solution was found to give satisfactory results. Penicillin therapy in a small number of instances showed much promise. One patient who failed to respond to Lugol's solution responded to penicillin. Resolution occurred in all but 1 of the early cases with either form of treatment, and abscess formation was more likely to develop in older cases of three or more days' duration before the start of therapy. Draining of abscesses is advised in conjunction with chemotherapy. Although 15 of the 49 patients died, in 13 of the 15 the parotitis had completely or partially resolved under chemotherapy without abscess formation before death occurred. The chief causes of death were the underlying primary diseases.

Resection of Duodenum and Head of Pancreas for Carcinoma.—Waugh and his co-workers point out that, largely because of the pioneering efforts of Whipple, a radical operation has been evolved for carcinoma in the region of the ampulla of Vater. This operation offers the patient a chance for cure not previously available. It consists in radical resection of the duodenum and head of the pancreas. The authors review 30 cases in which this operation was performed at the Mayo Clinic. The operative mortality in these cases was 20 per cent. The postoperative survival on short follow-up is disappointing in the cases in which the operation was done for carcinoma of the head of the pancreas but encouraging in those in which it was done for carcinoma of the ampulla of Vater. Although the one stage procedure is usually preferable, there is the occasional patient with severe damage to the liver who will require a two stage operation. Pancreaticojejunostomy, either end to end or end to side, has improved the prospect for normal nutrition postoperatively. Choledochojejunostomy usually is preferable to cholecystojejunostomy in the one stage procedure. Postcolic, antiperistaltic gastrojejunostomy made distal to the biliary and pancreatic anastomoses lends itself well to this type of resection and has proved most effective.

Thermal Burns: Effect of Altering Nitrogen and Caloric Intake or of Administering Testosterone Propionate.—Abbott and his co-workers summarize the impressions gained in studying the metabolic response of 45 burned patients and a group of animals with standardized experimental burns. This report is largely confined to the the effect on the nitrogen balance of altering the food intake or of administering daily 25 mg. of a nitrogen-retaining hormone (testosterone propionate). Following a thermal injury there is a fairly characteristic metabolic response, which is dependent on the severity of the injury and on the patient, his sex, age, previous nutritional state, therapy and complications. Diets with 3,000 to 5,000 calories and containing 100 to 300 Gm. of protein do not seem advantageous during the catabolic phase following a burn. In fact, such therapy seems to be harmful when given during the first week or two. Diets containing 1.6 times the basal caloric requirement (100 to 150 Gm. of protein) seemed to be tolerated quite well by the average patient. These patients had a smoother clinical course than did those on a higher intake; they maintained weight better and showed a smaller nitrogen loss than did the patients treated on a lower food intake. There is evidence that testosterone propionate may be of value in thermal injuries, although further investigation is necessary before such therapy can be advocated for routine use.

Tropical Acne.—According to Sulzberger as high as 10 per cent of all patients in military hospitals on Guam had skin diseases and from 60 to 70 per cent of ambulatory patients had skin disorders. Analysis of dermatologic cases revealed that approximately 20 per cent of the dermatoses are acnes. This is the more astonishing in view of the observation that most cases of acne seen in temperate climates tend to improve during the summer and in warm weather. The authors present observations on 51 consecutive cases of acne studied on the island of Guam. Although furuncles and furunculoid lesions may be present, the characteristic lesions of acne dominate the picture. There are blackheads, papules, nodules, pustules, cysts and often scarring. Despite the basic similarity with acne vulgaris the condition differs from adolescent acne vulgaris in several significant respects, namely its age of onset, its principal localization and its course. It is brought on or made worse by heat and high humidity and tends to improve when patients are removed to a cool dry environment. While poor personal hygiene, diet, local factors and infection may play some role, the occlusion of the ducts of hyperactive sebaceous glands seems to be the essential pathologic process.

Weltmann Coagulation Reaction in Rheumatoid Arthritis.—The Lucchesis and Bailonie think that Weltmann's serum flocculation band has not been sufficiently investigated in rheumatic diseases. They made this test 200 times in 85 cases, 66 of which (180 reactions) were cases of rheumatoid arthritis. They found that the sensitivity of the Weltmann reaction was practically the same as that of the sedimentation rate, the Weltmann reaction being only 2.8 per cent below the sedimentation rate. During the active stage of rheumatoid arthritis the Weltmann reaction showed a narrowed flocculation band; during the resting periods the band was normal. In rheumatoid arthritis the narrowing of the flocculation band was not as noticeable as in rheumatic fever. It occurred only up to tube 4. In rheumatoid arthritis the prognosis was favorable in cases which showed a normal or enlarged band, and it was unfavorable in cases showing a narrowed band. A favorable or reserved prognosis may in certain cases be advanced several months earlier, on the basis of the Weltmann reaction, than when the sedimentation rate is taken as a guide. In the terminal stage of rheumatoid arthritis there is a tendency toward an enlargement of the flocculation band.

Nodules of Rheumatoid Arthritis.—Fletcher reports a case in which nodules made their appearance on the head, neck, chest, abdomen, upper part of the arms, forearms, wrists, hands and legs of a man aged 42 four and a half years after he contracted rheumatoid arthritis. Biopsies were made of four subcutaneous nodules. There was present in all four specimens an area of complete necrosis in the center of the nodules, which, in three of the specimens, was surrounded by a cellular band containing numerous foam cells and many multinucleated and foreign body giant cells. Surrounding this again was a partly degenerated connective tissue band which contained, in addition to well defined foam cells, numerous inflammatory cells. In the other nodule the cellular zone was composed of fibroblasts arranged in a palisade manner. The vessels in the nodules and in the neighborhood showed endoarthritis, mesoarthritis and periarteritis. Cholesterol was present in the necrotic areas and the surrounding tissues. Fletcher suggests that probably the best description of the apparently unique nodules would be "necrobiotic nodules of the rheumatoid arthritis type with lipoid deposition."

Circumscribed Thyrotoxic Myxedema.—Lipman Cohen reports a case of circumscribed myxedema in a man aged 35 with mild thyrotoxicosis manifested by exophthalmos, nervousness, tremor, sweating, palpitation and relative lymphocytosis. On the anterior aspect of both legs there were roughly rectangular, poorly demarcated, raised bluish thickenings with yellow discoloration surrounding the lesions. These thickenings contained poorly defined firm swellings. The follicles were prominent and there were large flat, irregular, shiny translucent papules. When a biopsy was performed, mucin oozed from the incision. Thiouracil 1.2 Gm. was given daily for three weeks; administration of this drug was continued with 0.6 Gm. daily for two weeks and with 0.4 Gm. daily for nine weeks. The patient gained 14 pounds (6.4 Kg.) and his nervousness and tremor disappeared. The exophthalmos had greatly decreased. Changes in the skin were slight. The blue and yellow coloration had disappeared and the swellings were considerably softer but slightly bigger. Thiouracil will not cure this condition even when it controls the thyrotoxicosis completely. The name "myxedema circumscriptum thyrotoxicum" is suggested for the condition as being accurately descriptive and not too unwieldy.

Effect of Protein Deficient Diets on Rat Kidney.—Dicker and his associates investigated the kidney function of rats fed on vegetable diets that were deficient in protein. Kidney function tests were performed when the rats had been on protein deficient vegetable diets for about thirty-six days and when their plasma protein concentration had decreased from 7.58 ± 0.682 to 4.26 ± 0.097 Gm. per hundred cubic centimeters. Estimations of the total tubular excretory mass of rats on a protein deficient "turnip diet" gave figures which were significantly lower than those in normal rats, showing an impairment of the tubular diodone transfer mechanism. Urinary concentration and dilution tests revealed that the urine of rats on a standard diet reached a mean specific gravity of 1.070 ± 0.0037 after twenty-four hours of water deprivation. The same series of animals at the end of the period of protein deficient feeding excreted a urine of the mean specific gravity of 1.041 ± 0.0044. The results of the concentration and dilution tests are discussed with reference to the occurrence of visible edema in the animals on protein deficient vegetable diets and to the decreased water diuresis usually observed in hypoproteinemic rats. Renal lesions were found in many of the rats on protein deficient vegetable diets. They consisted of necrosis and calcification of the broad limbs of Henle; the glomeruli and other parts of the nephron showed no apparent change.

Estimation of Fecal Urobilinogen.—Maclagan treats fresh stool with ferrous hydroxide to convert stercobilin pigments to urobilinogen. The filtrate is heated with Ehrlich's reagent and sodium acetate, and the pink color is compared in either a photoelectric colorimeter or in a Duboscq type colorimeter against a neutral gray screen. Estimations in 120 cases are recorded. A study of the various possible sources of error indicates the importance of testing only fresh specimens. Normal values were from 30 to 220 mg. per hundred grams or from 22 to 121 mg. per day if estimated on four consecutive twenty-four hourly collections. Results were above normal in retention jaundice, malaria, untreated pernicious anemia and aplastic anemia, after fractures of long bones and in certain cases of infective jaundice; they were below normal in many cases of infective and obstructive jaundice. The value of the test as an index of hemolysis is discussed. When used for this purpose it may be desirable to combine the estimation with reticulocyte counts and/or serum bilirubin estimations.

Male Infertility.—Of the 512 consecutive cases of sterility seen by Jeffcoate in private practice 491 were investigated, and assessment of the husband's fertility was made in 320 of these. In the hospital series the husband's fertility was assessed in 115 of the 252 cases studied. Not less than one third of the husbands of infertile marriages have impaired fertility. Of the husbands examined by semen analysis 40 per cent showed evidence of subfertility. Responsibility for one pregnancy is unreliable evidence of a man's fertility. Impotence existed in 13, phimosis preventing coitus in 1 and faults in semen in 169. Impotence is more often due to psychologic disturbance than to physical disability or endocrine upset. The treatment of impotence consisted essentially in talks and discussions with the object of sorting out the underlying cause of the inhibition, explaining it and giving instruction on sex matters. This treatment proved effective in some of the cases. Sublingual administration of testosterone was largely ineffective. The causes of defects in production or delivery of spermatozoa are mumps, cryptorchism, venereal disease, varicocele and endocrine imbalance. In about half of the cases none of these causes could be found, and in these many possible etiologic factors have been postulated such as nutritional deficiencies and constitutional, occupational and environmental factors. In the absence of an obvious cause the treatment of faulty production of spermatozoa is for the most part empirical. Attention to general health and habits, hours of work and recreation is always important. Some form of glandular therapy is usually advised. Semen analysis before and after treatment with serum gonadotropin in 14 cases showed that in the majority of cases the quality of the semen improves after treatment and that it deteriorates again when treatment is suspended. These results, although suggestive, are not conclusive, and the possibility of spontaneous variations in the semen cannot be excluded. In the assessment of male infertility arbitrary standards for the various characters of the semen have to be adopted. Attention is drawn to the need for caution in the interpretation of the results.

Health of Children in Wartime Day Nurseries.—The Nurseries Committee of the Medical Women's Federation compared children who had been six months or more on the register of a wartime day nursery (nursery group I) with two other groups: (*a*) children who had been less than one week in a day nursery (nursery group II) and (*b*) children attending welfare centers. Wartime day nurseries were established with the object of augmenting the country's labor force. Admission was therefore limited in the main to the children of mothers in employment. Children who had been on the register of a wartime day nursery for six months or more had a much higher incidence of respiratory infection than those attending welfare centers in the same localities. The difference was present in all age groups and in both sexes. The 2 to 3 year old groups showed the greatest difference. The increase in respiratory infection was not attributable to significant differences between welfare center and nursery children at the start of their nursery life. On the other hand, the data show that the nursery children were on the whole heavier than the welfare center ones. More nursery children were recorded as "very fit" and "well" in the upper age groups than in the same age groups of welfare center children. The scope of the evidence is admittedly limited, but as far as it goes it does not indicate a beneficial effect of nursery life for the younger children—rather the reverse. The conclusion is reached that the high incidence of respiratory infection in wartime day nurseries constitutes a risk to health demanding careful consideration in weighing the value of day nursery life.

Painful Feet Syndrome.—Page directs attention to a condition known as painful, electric, hot or happy feet among prisoners of war in the Far East. It is ushered in by severe burning and aching of the feet associated with hyperesthesia, raised skin temperature and vasomotor changes in the feet, with general body wasting. The condition was first seen from three to five months after the Japanese occupation in the various countries in the Far East where large prison camps were established. No definite cause could be attributed at first, but protein, fat or vitamin deficiencies were considered as possible causes. A factor contained in grain was regarded as important when it was observed that men fed for months on rice with a rich admixture of barley did not develop painful feet, whereas their comrades fed on a poor grade of frequently musty rice did. The syndrome appears to be the result of a deficiency of factors in the vitamin B complex closely allied to the PP factor but primarily affecting the peripheral arteries of the lower extremities, or it might possibly be due to a toxic factor in old musty polished rice associated with a low protein intake and reduced vitality. The appearances in the early stages are similar to those of erythromelalgia. It is not an angioneurosis and is not associated with a neuropathic diathesis. The disease is amenable to treatment by replacement of the deficient elements in the diet; otherwise it is rapidly progressive, ending in death or serious crippling deformities.

Psychiatric Illness in Coal Miners.—Post and Lond report observations on 100 men employed in underground work in the mining industry who were treated at the Jordanburn Nerve Hospital. Anxious depressive psychoneurosis was observed in 30 patients, depressive psychosis in 18, persistent psychoneurosis including psychopathies in 14, organic psychiatric syndrome in 12, schizophrenic psychosis in 11, conversion hysteria in 10 and physical disease accompanied by psychiatric symptoms in 5. In more than half of the miners suffering from a psychiatric illness occupational factors were absent or unimportant from the point of view of etiology, and only few men broke down on account of the unpleasant and dangerous nature of underground work alone; on closer investigation deeply seated personality problems eclipsed in importance the occupational factor. The author thinks that observations made on psychologically ill men cannot be applied to miners as a group. There are the stabilizing factors of a corporative spirit and, especially in the face of danger, miners show a fine sense of comradeship. Yet there is also an atmosphere of disgruntled resentment and restiveness, which must provide a favorable culture medium for neurotic reactions.

Casein Hydrolysate for Premature Infants.—Jorpes and his associates gave a mixture of amino acids, an enzymic casein hydrolysate, as a supplement to breast milk to over 100 premature infants. Usually the daily dose was 2.5 Gm. of amino acids per kilogram of body weight, together with an equal amount of dextrose. The infants tolerated the amino acid mixture well. There were no signs of digestive disturbance. The feeding of this mixture of amino acids produced in every instance a distinctly higher gain in weight than breast milk alone. A comparison between the effects of this amino acid mixture and of a mixture containing undigested casein, dextrose and salts in the same strengths and proportions proved that the gain in weight was consistently greater during the periods when the infants were receiving amino acids than when casein was being administered. By special tests, in which neither dextrose nor salt mixture was added to the diet, it was demonstrated that the gain in weight was due to the amino acids. The results achieved indicate that by administering this supplementary food it is possible to shorten the hospital stay of these infants.

*Peptic Ulcer Treated with Gastric and Intestinal Extracts. O. Hubacher. —p. 272.

Syndrome Simulating Acute Abdominal Disease.—Goldstone and Le Marquand describe a series of cases in which the symptomatology indicated an acute abdominal condition. There was right upper abdominal pain and rigidity with pyrexia. The syndrome comes on in a few hours and frequently simulates a perforative lesion. Spontaneous recovery is the rule. In 1 of the 13 cases observed a perirenal abscess eventually developed. It is suggested that the cases in which spontaneous recovery occurred were abortive forms of perirenal staphylococcic infection. Abortive perirenal staphylococcic infection may be common in the silent perirenal fat, but symptoms do not arise unless the lesion touches the peritoneum. Cases simulating perforated peptic ulcer but negative on operation are not uncommon. They may be of the same type as those described here.

Gastric and Intestinal Extracts in Peptic Ulcer.—According to Hubacher enterogastrone, extracted from the intestinal mucosa, diminishes gastric secretion, decreases gastric motility and participates in the regulation of the blood supply to the gastric and duodenal mucosa. It largely prevents the development of the intestinal ulcers in dogs subjected to duodenoileac anastomosis and gastrojejunostomy. Urogastrone is a substance analogous to enterogastrone obtained from urine; it is found in decreased quantity in the urine of ulcer patients, and it has been assumed to represent an excretory form of enterogastrone. Independently of results obtained in the United States, extracts have been prepared in Switzerland from the stomach and small intestine of freshly slaughtered animals. The water soluble part of the extract is used for injection, and the water insoluble fraction is put up in tablets. The preparation for the treatment of gastric ulcer contains predominantly extract of stomach, whereas that for the treatment of duodenal ulcer contains principally extract of small intestine. Of 54 cases treated with these extracts 44 showed good results. All the cases which benefited by this treatment showed rapid disappearance of symptoms, increase in weight and rapid decrease in size of the ulcer niche as disclosed by radiography. These results were obtained without dietetic restriction or confinement to bed. It is suggested that the extract in tablet form can be used to supplement the injections or for prophylactic treatment.

*Aninsulin P Barral —p 374
Aleukia Resulting From Ingestion of Toxic Food New Disease Described in URSS L C Brumpt —p 375

Aninsulin—Barral produced aninsulin by exposing insulin to the combined action of heat and formaldehyde Administration of aninsulin to rabbits, horses and human subjects revealed that aninsulin in concentration of 2 cc in 1 liter of isotonic solution of three chlorides to 10 cc per thousand is a vasoconstrictor, while insulin in a concentration of 2 cc per liter is a vasodilator and becomes a vasoconstrictor only with much higher concentration Aninsulin is not hypoglycemic and is not toxic It retains the trophic power of the insulin One injection of 0 2 to 0 5 cc of aninsulin every two days proved sufficient to stimulate cicatrization of indolent postoperative wounds and of ulcers of the leg Aninsulin increases the complement power of serum and has a pronounced antigenic power. A true Arthus phenomenon was produced in rats with Jensen's sarcoma by injection of aninsulin The existence of an antibody "antianinsulin" was demonstrated in the serum of certain patients with cancer

Electroencephalographic Study of Comatose States H Fischgold and G Bounes —p 1245
Analysis of Cerebral Frequencies L Bugnard —p 1247

Electroencephalographic Diagnosis of Epilepsy.—Baudouin and his associates state that specific paroxysmal patterns in the electroencephalogram, such as alternating wave spike complex, solitary spikes or sudden and transient spikes, are suggestive of epilepsy Paroxysmal irregularities consisting of a sudden emission of more or less symmetrical sinusoidal slow waves make epilepsy very likely in persons with attacks in the absence of other neuropsychic symptoms Definite deviations from the normal electroencephalogram may be present hours and days after a clinical paroxysm A favorable prognosis may be made on the simultaneous disappearance of these encephalographic changes and of the clinical symptoms as a result of adequate treatment while prognosis is uncertain in cases in which the encephalographic changes persist in the absence of clinical symptoms Normal electroencephalograms were observed in 20 per cent of persons with established diagnoses of epilepsy, particularly in persons of advanced age, in secondary epilepsy and in persons in whom the electroencephalograms were made a long time after the epileptic attack The diagnosis of epilepsy is uncertain in a young untreated person presenting a grand mal attack but whose electroencephalogram made a few hours after the attack is normal Only in persons over 20 years of age does the electroencephalogram assume its definite adult character Before this age many persons may still present the infantile type of the electroencephalographic record In the latter cases electroencephalograms should be interpreted with utmost caution with regard to the diagnosis of epilepsy

Electroencephalography of Brain Tumors—Baudouin and his associates studied electroencephalograms of 113 cases of brain tumor which were confirmed by ventriculography, surgical intervention or necropsy Sixty-four of these were tumors of the hemispheres The exact site of the tumor was demonstrated in 34 and the hemisphere involved was demonstrated in 9 A more or less definite localization has been possible in 67 per cent of the cases The encephalogram proved inadequate in 6 cases, diffuse generalized electrical changes prevented the localization of the tumor in 9, normal electroencephalograms were observed in 3, while in 3 cases the localization of the tumor was erroneous In the absence of clinical symptoms the electroencephalogram provides important information in cases in which the right temporal or the frontal lobes ("silent zones") are the site of the tumor Electroencephalography may replace cerebral ventriculography in a limited number of cases in which the electrical observations correspond to the clinical symptoms The electroencephalogram is of prognostic value with regard to immediate prognosis and the postoperative course In 21 cases of tumor of the base the value of the electroencephalogram was inferior to that of the roentgenologic and ophthalmologic examinations In 26 cases of tumor of the posterior fossa the electroencephalogram was of considerable prognostic value A totally altered electroencephalogram in which the alpha rhythm has disappeared suggests a grave disturbance in the brain and an unfavorable prognosis with regard to surgical intervention

*Chemically Detoxicating Action of Sulfonamides an Apparently Disregarded Characteristic Preliminary Report P Robert and V Stettler —p 488
Prophylaxis with Sulfonamides in Obstetrics H Aeppli —p 490

Endocrinology of Tumors of Adrenal Cortex—The observation of an endocrinologically active hypernephroma with Crooke's hyaline change in the pituitary basophils and with diabetes insipidus gave Buchler the opportunity to call attention to the clinical identity of Cushing's syndrome in hypophysial basophilism and in tumors of the adrenal cortex Differentiation between basophilic adenoma and interrenalism is impossible on the basis of the clinical characteristics, except that hypertrophy of the clitoris and severe hirsutism is more characteristic of hypernephroma The author describes the peculiar changes in the pituitary basophils described by Crooke in 1935 and stresses their significance as the only anatomic change in the endocrine apparatus that is found in all forms of Cushing s syndrome He points out that the demonstration of diabetes insipidus by Redlich and by himself represents an extension of the symptomatology of hypernephroma but the pathogenesis of the hypernephrogenic disturbance in the water exchange has not been explained as yet A hypophysial-diencephalic genesis is considered possible but in view of the simultaneously existing osteoporosis nephrocalcinosis and hyperplasia of the parathyroids the possibility of a parathyrogenic diabetes insipidus is taken into consideration

Detoxicating Action of Sulfonamides.—Robert and Stettler, observing that arsphenamine erythrodermia rapidly improves under sulfonamide treatment, suggested that in analogy to the sulfur therapy of toxicodermias the sulfur component of the sulfonamides may have a detoxicating effect. Since they were unable to find reports on this problem, they decided to investigate this assumed effect of sulfonamide compounds on the basis of the well known example of the detoxication of potassium cyanide by sulfur with formation of rhodan. It is well known that sodium thiosulfate, which readily splits off sulfur, is the best detoxicating agent in potassium cyanide poisoning. The authors made experiments on rabbits, administering the poison as well as a detoxicating sulfonamide preparation by intravenous injection. A decided protective action was exerted by the sulfonamide. It is believed that the detoxication takes place by way of rhodan formation. Sulfur probably plays an important part in the new chemotherapeutics and antibiotics.

**Treatment of Gastric and Duodenal Ulcers with Female Sex Hormones.* W. Friedlaender.—p. 231.
Cancer of Stomach: Clinical and Radiologic Considerations. M. A. Bellini.—p. 242.
Penicillin in Treatment of Syphilis. J. M. Tiscornia Denis.—p. 254.

Female Sex Hormones in Gastric and Duodenal Ulcers.—Friedlaender reports 5 cases of gastroduodenal ulcer in which he resorted to the use of female sex hormones. He gives his patients two weekly injections of 2.5 mg. of diethylstilbestrol or of 5 mg. of estrogenic substance for three weeks. After the sixth injection he gives one weekly injection for an additional period of four weeks. The pain is usually favorably influenced after the fifth or sixth injection. If there is no improvement after ten injections the treatment must be regarded as a failure. Some patients may have a slight swelling of the mammary glands and others may have temporary impotence, but both of these effects subside after treatment is stopped. The diet needs to be much less strict when estrogens are given than is the case in the classic Sippy treatment. It may include soups, purees, potatoes, vegetables, chicken, sweets, honey, compotes and the like. As a result of this more generous diet the patient's general condition is better, his weight increases and he has a better appetite.

*Penicillin in Empyema Following Pulmonary Exeresis: Prophylactic and Curative Value in 203 Cases. L. Langer, E. Naclerio and F. E. Tricerri.—p. 1140.

Penicillin in Prevention and Therapy of Empyema Following Resection of Lung.—Two hundred and three patients with pulmonary disease (bronchiectasis, cancer, tuberculosis and chronic suppuration) were subjected to partial or complete lobectomy or to pneumonectomy. In 100 patients 10 or 15 Gm. of sulfonamide was placed in the pleural cavity during the operation. One hundred and three patients received preoperatively intramuscular injections of 15,000 units of penicillin every three hours up to a total daily dose of 120,000 units for a period of from two days to two weeks, during which the patients were also given inhalations of penicillin solution in a dose of 20,000 units every three hours up to a total daily dose of 100,000 units. They also received intramuscular injections of penicillin after the operation for one or two weeks. Empyema developed in 13 per cent of the patients treated with sulfonamide and in 13.6 per cent of those given penicillin. These patients were treated with intrapleural administration of penicillin in daily doses of 40,000 units. Pulmonary empyema complicated pneumonectomy in 17.2 per cent, segmental resection in 40 per cent and lobectomy in 2 per cent. In empyema following pneumonectomy, penicillin was administered for as long as the pleural secretion was serosanguineous. As soon as the fluid became purulent, surgical drainage was resorted to. Empyema after resection of the lung seems to be dependent on the failure of the bronchial stump to close.

Physicochemical Foundations of Phenomena of Allergy and Immunity. J. L. Alvarez Sala.—p. 224.

Nicotinic Acid and Gastric Secretion.—Díaz-Rubio and his associates say that in treated pellagrous subjects they observed no improvement in secretion, achlorhydria remaining as before. In investigations on the action of nicotinic acid they found that the intravenous injection of nicotinic acid produces an increase of free acidity in the gastric juice in normal subjects, and in sufferers from achylia it causes the appearance of acidity. In achylia of pellagra no effect on the acidity is produced but only an increase in the quantity of the gastric juice. The authors think that this action of nicotinic acid is due to the greater vascularization it produces in the walls of the stomach, which in turn stimulates the secretory glands of the stomach. In patients with pellagra, however, the tonus of the sympathetic is lowered, and it is this factor which may explain the lack of response to nicotinic acid in these cases.

Pyoderma Gangrenosum.—Kristiansen describes a rare disease which appears as a rapidly advancing gangrene of the superficial layers of the skin, with central necrosis, granulation tissue and intervening epithelial islands and peripheral undermining of the epidermis. It is accompanied with hypochromatic anemia and increased sedimentation reaction. The general condition is as a rule unimpaired. The regional lymph nodes are not affected. The disorder seems to predominate in women of ages between 16 and 60, and the duration is usually from nine to over twelve months. To date only 1 fatal case has been reported. If the course is not threatening, conservative treatment with sulfathiazole locally and by mouth is advised. In the personal case described there were dilated lymph vessels partly covered with epithelium derived from the surface epithelium.

Book Notices

Enzymes and Their Role in Wheat Technology. Edited by J. Ansel Anderson. American Association of Cereal Chemists, Monograph Series, Volume I. Cloth. Price, $4.50. Pp. 371, with illustrations. New York: Published by Interscience Publishers, Inc., for the American Association of Cereal Chemists, 1946.

The per capita consumption in the United States of the milled products of wheat is about 160 pounds each year. The principal converted products of wheat are bread and other bakery products. For more than twenty years it has been recognized that the enzymes which naturally occur in wheat have a significant effect on the baking characteristics of the flour. It is appropriate, therefore, that the first volume in the series of scientific monographs now being sponsored by the American Association of Cereal Chemists should be concerned with the enzymes of this important basic food.

The volume is divided into eleven chapters, the first of which, by W. M. Sandstrom, comprises a general discussion of the chemistry of enzymes. C. H. Werkman discusses the mechanism of alcoholic fermentation, and the subject of yeast fermentation is adequately handled by Lawrence Atkin, A. S. Schultz and C. N. Frey. The remaining chapters are concerned with amylases, esterases, oxidizing enzyme systems and proteases. Each of these subjects is discussed first from the general point of view and then from the point of view of its application to milling and baking technology. This division is a happy one because it permits a well rounded treatment. Thus, Mary L. Caldwell and Mildred Adams present a general review of the significance of amylases in plant and animal tissues. The application of the amylases in milling and baking technology is handled by Eric Kneen and R. M. Sandstedt. Herbert E. Longenecker contributes a chapter on esterases, and Betty Sullivan a chapter on the relation of esterases to milling and baking. In a remarkably brief section E. S. Guzman Barron presents a fairly comprehensive summary of current information about oxidizing systems, while Betty Sullivan reviews the scattered information about oxidizing enzyme systems of wheat and flour. Proteases are discussed by A. K. Balls and Marion W. Kies. The role of proteases in baking is treated by F. C. Hildebrand. Each chapter concludes with a selected bibliography. The book is adequately indexed as to both subjects and authors.

There is thus produced a well rounded volume that should be of interest and value to biochemists generally as well as to investigators in the field of enzymes and in the science of milling and baking. The cereal chemists are to be commended for having so successfully inaugurated a worth while program of sponsoring authoritative monographs in the science and technology of an important class of foods.

Advancing Fronts in Chemistry. Volume II. Chemotherapy. Edited by Wendell H. Powers, Assistant Professor of Chemistry, Wayne University, Detroit. Contributors: William H. Feldman and others. A Series of Lectures Sponsored by Wayne University under the direction of Neil E. Gordon, Chairman, Department of Chemistry. Cloth. Price, $3.25. Pp. 156, with illustrations. New York: Reinhold Publishing Corporation, 1946.

This volume is the second in a series of lectures delivered by competent authorities at Wayne University under the direction of Dr. Neil E. Gordon, chairman of the department of chemistry. The first volume consisted of lectures in the field of high polymers. The present volume includes lectures presented in 1945 by six writers on various phases of chemotherapy. Unfortunately, the lecture on antibiotics delivered by Dr. H. E. Carter of the University of Illinois is not included.

The first lecture, on chemotherapy in experimental tuberculosis, by Dr. William H. Feldman of the Mayo Foundation, is an excellent survey of the field. Dr. Feldman, in critical fashion, expresses the difficulties encountered in interpreting experimental and clinical results in the therapy of tuberculosis. The second lecture is a highly technical consideration of synthetic antispasmodic drugs by Dr. Frederick F. Blicke of the University of Michigan. Dr. E. H. Northey of the American Cyanamid Company presents an informative discussion on the chemistry of the sulfonamide drugs. The antimalarial problem is the timely subject considered by Dr. Harry S. Mosher of Pennsylvania State College, and Dr. C. Kenneth Banks of Parke, Davis & Company chose as his subject organometallic compounds as chemotherapeutic agents. The series concludes with a consideration of past developments and present needs in the chemotherapy of parasitic diseases, by Dr. Willard H. Wright of the U. S. Public Health Service.

The volume is well edited. Each of the chapters is preceded by a bibliographic sketch of the lecturer and succeeded by references to the literature. An excellent index concludes the volume. This series of informative lectures should be a welcome addition to the library of the physician who wishes to keep abreast of the newer developments in the field of medicine.

Psychological Medicine: A Short Introduction to Psychiatry, with an Appendix on Psychiatry Associated with War Conditions. By Desmond Curran, M.B., F.R.C.P., D.P.M., Psychiatrist and Lecturer in Psychological Medicine, St. George's Hospital, London, and Eric Guttmann, M.D., M.R.C.P., Neuropsychiatric Specialist, Emergency Medical Service, London. Foreword by J. J. Conybeare, M.C., D.M., F.R.C.P. Second edition. Cloth. Price, $3.50. Pp. 246, with 20 illustrations. Baltimore: William Wood & Company, 1945.

In the past year there have appeared a number of small manuals on psychiatry which have had considerable worth not only to the psychiatrist but to the physician who is interested in psychologic problems, particularly psychosomatic medicine. The authors of the present book are highly qualified British practitioners who have made contributions before. It is natural that since there are less than 250 small pages the subject cannot be covered completely. For physicians in this country it must be considered inferior to several American books on neuropsychiatry. The problem, for instance, of anxiety neurosis is not very well covered, while the psychoses are discussed in considerable detail. Some organic entities are completely neglected. The British slant is slightly different from ours: there is less emphasis on strictly freudian psychology, and the present authors have a definitely organic slant on certain conditions, such as neurasthenia, which has not been emphasized here. The book is too small for adequate discussions of shock treatment and psychotherapy. It is a substantial book from the standpoint of honest effort, and except for the differences which must occur between nations even in scientific subjects, and except for the need for cutting down information by virtue of its size, it can well be considered an adequate small psychiatric textbook.

Spezielle chirurgische Therapie für Studierende und Ärzte. Bearbeitet von Dr. Max Saegesser. Sammlung medizinischer Lehr- und Handbücher für Ärzte und Studierende. Band II. Cloth. Price, 80 Swiss francs. Pp. 884 with illustrations. Bern: Hans Huber, 1946.

As the title indicates, this is a manual of surgical treatment. Without discussing pathology or diagnosis, it tells what should be done in each specific surgical condition described, and how it is best to do it. The technic, preoperative and postoperative management, the possible pitfalls and how to avoid them are described in step by step detail. The work is up to date, written in clear and simple language, easily understood and followed by students for whom it is intended. The subjects covered in some of the twelve chapters are surgical treatment of diseases of the head, scalp and face and diseases of the chest, the abdomen and the urinary and genital organs. Also covered are injuries and diseases of the bones, joints and spine, as well as those of the blood vessels and peripheral nerves. In the belief that more can be learned from pictures than from words, there are numerous descriptive pen and ink illustrations, which greatly enhance the clarity and value of the text. This book is an excellent and useful addition to the surgical textbooks on this subject.

The Common Sense Book of Baby and Child Care. By Benjamin Spock, M.D. Cloth. Price, $3. Pp. 527, with illustrations by Dorothea Fox. New York: Duell, Sloan and Pearce, 1946.

The popular literature on child care has undergone a remarkable improvement in the past decade. From the dogmatic instructions to bewildered mothers on how to bathe, dress and prepare a complicated formula for the infant of a generation ago, recent publications have shown almost uniformly a more logical tendency with emphasis on understanding of principles rather than on exhortations to follow routine directions. There are today many such books on the market written mostly by pediatricians and psychologists, each giving his views in behalf of better care of the infant and child. The common objective is to make child rearing free from unnecessary anxieties and at the same time cultivate a generation of happier, if not wiser, people.

Apparently with this aim Spock developed the theme of his book. He has incorporated the experiences of a sensible pediatrician into a volume which is an excellent treatise on the subject. Unlike many authors who are inclined to overemphasize some pet subject in which they happen to be most interested at the moment, Spock's pet subject seems to be the child as a whole unit. And as he is attempting to afford the child the benefits of wholesome care, he talks plain common sense to all who constitute the child's social and biologic setting from its earliest embryonic development through adolescence.

The style is simple yet thoroughly informative. The author does not indulge in speculative discussions. He has the happy ability of stating a point, developing it sufficiently to be understood by any person with normal intelligence, then proceeding to the next topic and the next, and so on. The subject matter is well organized. Throughout there is a palpable effort to interpret the child to a world of grown-ups. A most laudable feature in this connection is the discussion of the various phases of health and its possible aberrations at different age levels. The advantages of this arrangement are obvious. It not only affords parents an idea on what they may expect at a particular developmental level but also gives them the opportunity to familiarize themselves with the problems of immediate interest to them.

The advice "If you cannot get a doctor" and "consult your doctor" appears too frequently and is cumbersome and unnecessary. As a general rule people who read books of this type seldom rely on self medication. With the exception of this minor criticism, the book is by far the most instructive as well as the most practical in its field. It may be heartily recommended not only to parents but to physicians as well. Dr. Spock is to be congratulated on a difficult task exceptionally well accomplished.

Studies in Brazilian Anophelines from the Northeast and Amazon Regions. I. An Illustrated Key by Adult Female Characteristics for the Identification of Thirty-Five Species of Anophelini, with Notes on the Malaria Vectors (Diptera, Culicidae). By L. M. Deane, O. R. Causey and M. P. Deane. II. An Illustrated Key by Male Genitalic Characteristics for the Identification of Thirty-Four Species of Anophelini, with a Note on Dissection Technique. By O. R. Causey, L. M. Deane and M. P. Deane. III. An Illustrated Key by Larval Characteristics for the Identification of Thirty-two Species of Anophelini, with Descriptions of Two Larvae. By M. P. Deane, O. R. Causey and L. M. Deane. The American Journal of Hygiene Monographic Series, No. 18, February 1946. The publication of this monograph (No. 18) was financed by the Office of InterAmerican Affairs. Cloth. Price, $1.10. Pp. 58, with illustrations. Baltimore: Johns Hopkins Press, 1946.

This monograph consists of keys for species of Anopheles mosquitoes, both malaria carriers and those of no importance in the transmission of malaria. The malaria vectors represented are Anopheles gambiae, Anopheles aquasalis and Anopheles darlingi. The first part is devoted to the adult female characteristics of thirty-five species, the second part to the male genitalic characteristics of thirty-four species and the third part to the larval characteristics of thirty-two species of Brazilian Anophelini. The keys are accompanied with numerous drawings and photographs of the characteristics most needed for purposes of identification of these mosquitoes. The larvae of two species (Anopheles galvaoi and Anopheles shannoni) are described for the first time.

Gynecologic Nursing. By Robert James Crossen, A.B., M.D., F.A.C.S., Assistant Professor of Clinical Gynecology and Obstetrics, Washington University School of Medicine, St. Louis, Mo., and Frances W. Hoffert, R.N., B.S. Third edition. Cloth. Price, $2.50. Pp. 256, with 191 illustrations. St. Louis: C. V. Mosby Company, 1946.

The third edition of this popular gynecologic textbook for nurses follows the popular plan of co-authorship by a physician and a nurse. This is the best approach to the successful teaching of the medical specialties to nurses. The senior author is the co-author of several popular textbooks on gynecology and brings to this nursing textbook the benefit of his wide experi- It is easy to read and extensively illustrated. In its l plan the book follows the Curriculum Guide prepared by the National League for Nursing Education. Part I presents a survey of the basic knowledge of anatomy and physiology of the reproductive organs. Part II concerns itself with the various gynecologic diseases as well as the common diagnostic procedures. Nursing procedures are emphasized. Review questions and a short bibliography accompany each chapter. This edition should retain the popularity of previous editions.

A Short Practice of Surgery. By Hamilton Bailey, F.R.C.S., F.I.C.S., Surgeon, Royal Northern Hospital, London, and R. J. McNeill Love, M.S., F.R.C.S., F.I.C.S., Surgeon, Royal Northern Hospital, London. Seventh edition. Cloth. Price, 40s. Pp. 1,097, with 1,063 illustrations. London: H. K. Lewis & Co., Ltd., 1946.

The title is perhaps misleading. This is a volume containing over a thousand pages and over a thousand illustrations. It is a complete textbook of surgery from which has been deleted much of the superfluous and ancient material contained in other textbooks. It is concise, is clearly written and makes excellent reading material. The paper, binding and typography are very good, particularly in view of its production in a country ravaged by war for so many years. The seventh edition has been enlarged and brought up to date and contains much very new material. A new chapter on the larynx has been included. The illustrations, almost one fifth of which are colored, are excellent and help greatly in making the text more readable and understandable. The index is inclusive (fifty-one pages). The small glossary giving the old terminology of anatomic names should be helpful to many readers. Another interesting feature is the inclusion of brief biographic footnotes. Lack of bibliography is really the one thing that makes this volume a "short" practice rather than an excellent textbook.

Autopsy—Diagnosis and Technic. By Otto Saphir, M.D., Pathologist, Michael Reese Hospital, Chicago. Foreword by Ludvig Hektoen, M.D. Second edition. Fabrikoid. Price, $5. Pp. 405, with 69 illustrations. New York & London: Paul B. Hoeber, Inc., 1946.

This edition, like the first of 1939, furnishes medical and graduate students in pathology concise yet clear descriptions of procedures in the performance of the necropsy and the common gross changes that may be seen. The illustrations cover technic and anatomic relations important in the observation and removal of normal and pathologic structures. Eighteen different tables are designed to classify and differentiate by distinctive characteristics the common lesions in the important organs. In this edition the discussion on diseases of the breast and the changes in stillbirths and newborn infants are extended. Brief chapters are added on examinations of the nose and sinuses and on anatomic changes in vitamin deficiencies and certain tropical diseases. Like many new books and revised editions the changing findings of the patient and appearances of viscera at the necropsy due to chemotherapy or antibiotics are not mentioned or described. However, the book is an excellent aid and a reliable, quick reference work for the student who finds the ordinary textbook on pathology inadequate in the description of the necropsy.

Proceedings: Conference on Diagnosis in Sterility Sponsored by the National Committee on Maternal Health, January 26-27, 1945, New York City. Edited by Earl T. Engle. Fabrikoid. Price, $5. Pp. 237, with illustrations. Springfield, Illinois: Charles C Thomas, 1946.

This small volume presents a copy of the Proceedings of the Conference on Problems of Human Fertility held under the auspices of the National Committee on Maternal Health in January 1945. Papers in the first group are devoted to an evaluation of gonadal functions in the male by a study of the semen and testicular biopsies. The role of the accessory glands in fertility in the male is discussed by Huggins. Papers in the second group concern themselves with diagnostic methods for evaluating fertility in the female. Endometrial biopsies, basal body temperatures, methods of studying tubal patency and the cervical mucus as a factor in sterility are discussed. Each of these papers is presented by a well known authority in his special field. A general discussion by the members of the conference is included. Treatment of sterility was not considered at this meeting. These conferences, sponsored by the National Committee on Maternal Health, on problems of fertility provide an excellent means for an interchange of ideas by the many workers in this special field.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

IMMUNIZATION OF BABY FOR TRIP TO JAPAN

To the Editor:—Advice is sought by the wife of an army officer on the advisability of taking a baby to Japan. What dosage of yellow fever, cholera and other immunizations should be given a 6 months old baby?

M.D., Alabama.

Answer.—Taking a healthy 6 months old baby to Japan would seem permissible if the father can assure himself in advance that suitable sanitary living accommodations are available. Taking younger babies at this time is wisely being discouraged by the army medical authorities. Yellow fever immunization is not necessary unless the child is to be taken through one of the yellow fever areas of South America or Africa as delineated officially by UNRRA under the International Sanitary Conventions. Neither Japan nor any place traversed by travel across the Pacific is in such an area. The dosage of yellow fever vaccine of standard type (17 D) for an infant is the same as for an adult, as the material is a living, modified virus. Administration can be arranged at several centers through the United States Public Health Service. Smallpox vaccination of infants going to the Orient is definitely necessary and is required. It is also recommended that infants be given diphtheria toxoid. Cholera and plague vaccinations are not insisted on or recommended for young infants.

HAZARDS OF PHOTOENGRAVING

To the Editor:—A photoengraver has had a morning cough over a period of years which at times causes him to vomit. Repeated roentgenograms of the chest have been negative and there does not seem to be any reason for this cough. Some time ago he passed a bloody stool, and a gastric series revealed a duodenal ulcer. After prolonged ulcer management the ulcer has healed, but the patient continues to cough. With what fumes would he come in contact with in photoengraving? Would these fumes affect his general health?

Leo B. Sedlacek, M.D., Cedar Rapids, Iowa.

Answer.—The trade of photoengraving has become so complex and so many processes and different substances are utilized that it is necessary to learn from the patient what chemicals are used by him. Long ago Hayhurst recorded that "photoengravers as a class are probably exposed to the greatest number of poisonous substances to be found in any single industrial calling." Earlier statistical records indicate a high frequency of respiratory disorders. Among other materials likely to be involved are mineral and organic acids, ammonium and bromium compounds, aniline, benzene, naphtha, chromium compounds, alkalis, chlorinated compounds including chloroform, cyanides, sulfides, formaldehyde, glues, gums, albumin and varnishes. The most likely single offender seems to be nitric acid or nitric oxides. In addition to possible direct respiratory tract irritation, some of the agents mentioned are sensitizers.

PENICILLIN FOR DIABETIC FURUNCULOSIS

To the Editor:—What is the present status of the use of penicillin, orally or parenterally, in the treatment of diabetic furunculosis?

Samuel S. Schept, M.D., Union City, N. J.

Answer.—The use of penicillin parenterally for the treatment of furunculosis in patients with diabetes has been highly satisfactory. In addition to penicillin, restrictions of diet and extreme care of the skin are important features. Most of the treatment that has been carried forward has been with the use of parenteral penicillin. If oral penicillin is used, at least three to five times as much will be needed.

USE OF OXYGEN FOR PENICILLIN AEROSOL

To the Editor:—A number of articles on the administration of penicillin vapor or aerosol penicillin have suggested the use of oxygen. Is oxygen necessary or would compressed air serve as well?

Charles E. Atkinson, M.D., Banning, Calif.

Answer.—Oxygen is used to aerosolize the penicillin. It is not necessary to use oxygen for this purpose, and air under comparable pressure can be used for the same purpose.

PENICILLIN FOR ERYTHREMIA

To the Editor:—Is penicillin effective in the treatment of erythremia? A white man aged 67 was treated several years ago for hypertension and cerebral hemorrhage. For the past six months he has complained of weakness, easy fatigue, headache, vertigo, dyspnea, sweating, partially dulled mental powers and a general run down condition. The blood pressure was 180/100, and the spleen and liver were not palpable. A diagnosis of erythremia was made on the basis of the symptoms and the finding of hemoglobin 115 Gm. per hundred cubic centimeters Sahli, red blood cells 6,500,000, white blood cells 16,000 and a normal differential with no abnormal cells. The patient was given intramuscular penicillin injections of 200,000 units once daily for eight days. One week after the completion of this treatment the patient reported that he felt much improved and the blood count fell to red blood cells 5,060,000, white blood cells 12,000 and hemoglobin 100 Gm. per hundred cubic centimeters.

Nicholas A. Mandelos, M.D., Washington, D. C.

Answer.—In the 13,000 cases reported to the Committee on Chemotherapeutics and other Agents, National Research Council, and the Committee on Medical Research of the Office of Scientific Research and Development concerning the use of penicillin in various disorders, none with erythremia were treated with penicillin. It will, of course, be necessary to follow the patient referred to in the query for a much longer time to determine whether or not the decrease in the red blood cell count and hemoglobin are permanent.

FINGER INFECTIONS IN EGG POWDERING PLANT

To the Editor:—During the last four years a number of people in this city have developed infections of the fingers, the cause of which has not been determined. An egg powdering plant is located here. Several people working in the plant have acquired severe infections which eventually have required amputation.

L. L. Roberts, D.V.M., Chanute, Kan.

Answer.—The files of the Office of Dermatology of the U. S. Public Health Service do not contain records of infections similar to those described in the query among workers engaged in powdering eggs.

To determine the actual cause of these infections, studies of the occupational process should be made, including bacteriologic studies of the products in the various stages of the process, and correlation of these results with the occupation of the workers affected and the organisms causing the infection. In Occupational Diseases of the Skin by Schwartz and Tulipan there is a chapter on methods of investigation of occupational diseases of the skin.

An effective method of prevention before the actual cause is discovered consists in wearing rubber gloves, impervious sleeves and aprons, and frequent washing of the hands with soap and water followed by dipping the hands in a mild antiseptic solution.

SODIUM TETRATHIONATE FOR ACUTE THROMBOANGIITIS OBLITERANS AND MIGRATING PHLEBITIS

To the Editor:—In the June 29, 1946 issue of The Journal the use of sodium tetrathionate in the treatment of superficial migrating phlebitis is mentioned. Please discuss dosage, mode of administration and action and give references.

S. Davidson, M.D., Boynton Beach, Fla.

Answer.—Sodium tetrathionate has been advocated by Theis and Freeland (Thromboangiitis Obliterans: Treatment with Sodium Tetrathionate and Sodium Thiosulfate, *Arch. Surg.* **40:**190 [Feb.] 1940) particularly in acute cases of thromboangiitis obliterans. They found an increase in skin temperatures, a decrease in pulse rate and increase in the oxygen carrying power of the blood; it counteracted the effect of smoking on the vascular system. They have also used this drug—which has a more delayed but also more prolonged action than sodium thiosulfate—in the treatment of arteriosclerosis, Raynaud's phenomena and other forms of vascular disease. It is quite possible that this strong reducing agent does affect the clotting mechanisms; de Takats (*Surgery* **14:**661 [Nov.] 1943) showed that it increased the patient's response to heparin. Others (Allen, Barker and Hines: Peripheral Vascular Diseases, Philadelphia and London, W. B. Saunders Company, 1946) have questioned the value of the drug.

Clinically, in the acute exacerbations of migrating phlebitis or thromboangiitis obliterans daily injections of sodium tetrathionate maintained for ten to fourteen days seem to alleviate the symptoms and bring on a remission faster than it spontaneously occurs. It does not cure the disease but acts somewhat like foreign protein therapy, though without chills, fever and other complications. Occasionally a patient may become dizzy or nauseated, and once in a great while a sensitization reaction may occur. The drug contains 44 per cent organic sulfur; it comes in ampules containing 0.6 Gm. in the form of a dry powder, which is dissolved in 10 cc. of sterile distilled water and slowly injected intravenously. One injection may be given twice a day in hospitalized and once a day in ambulatory patients for ten to fourteen days. If this is effective, injections can be continued for another two weeks. It is a good preparatory measure for patients in the active stage of thromboangiitis obliterans before sympathectomy is undertaken.

MAMMARY HYPERTROPHY IN INFANTS

To the Editor:—A girl aged 6 months has had enlarged breasts since birth. In the past few months the breasts have grown more rapidly to their present size of hickory nuts. They are firm to palpation and do not appear to be simply fat tissue. Vulvar enlargement and colostrum secretion are absent. Because of allergic eczema the infant was given goat's milk, which relieved the eczema immediately. Apparently the acceleration of breast growth began with the use of the goat's milk formula. Is there evidence that goat's milk contains an estrogenic substance in quantities sufficient to produce this effect? Should an ovarian tumor be suspected?

M.D., New York.

ANSWER.—As far as known there is not any relationship between the ingestion of goat's milk or of any animal milk to the mammary enlargement noted in the infant described in the query.

In the neonatal period mammary hyperplasia with some secretion is common in breast fed infants. This is most commonly encountered during the second week of life and may continue as late as the third month. This infantile mammary secretion, when examined, has been found to be chemically similar to human colostrum. It is said to be due to two hormones which are transmitted to the fetus through the placenta, namely estrogen from the ovary, which produces the breast hypertrophy, and prolactin from the mother's pituitary, which causes the colostrum-like secretion. Both of these endocrine substances have been demonstrated in the urine of infants during the first few days of life. This neonatal mammary hypertrophy and secretion of "witch's milk" have been noted equally in male and female infants.

Precocious mammary development may be caused by pituitary, adrenal, ovarian, renal and pineal hyperplasia or tumors. Endocrine therapy may also be a cause; however, the excessive breast development from such causes is accompanied by early appearance of pubic and maxillary hair and genital overdevelopment. As hirsuties and abnormal sexual development are stated to be absent in the infant under question, it seems unlikely that a tumor would be the cause of the breast enlargement. It might be well to analyze the urine of this infant for an increased amount of estrogenic substances. Further, as the enlargement is bilateral, it is improbable that a local growth is present. Well fed, well developed normal infants often exhibit bilateral enlargement of the breast area.

PROGRESSIVE MUSCULAR DYSTROPHY

To the Editor:—A woman in her early fifties on the faculty of one of the country's large universities has suffered for many years from progressive muscular dystrophy. This was first noticed years ago in her arms. However, during the past few years she has been progressively losing the use of her legs. It is now difficult for her to rise from a chair, and, when standing, her legs are unsteady. She has been on large doses of brewers' yeast and 100 mg. of thiamine hydrochloride daily, together with 15 Gm. of aminoacetic acid. In spite of this her condition is becoming gradually more severe.

M.D., New York.

ANSWER.—A specific form of treatment has not been devised for progressive muscular dystrophy. Recently the effect of vitamin E has been estimated by a considerable number of observers. In general the results obtained by using vitamin E in the form of alpha tocopherol, or the synthetic product d, l-alpha tocopherol acetate, have not been good. A few reports, following the use of large doses, have been slightly encouraging.

Shank and his colleagues used aminoacetic acid, vitamin E and pyridoxine in the treatment of 40 patients with progressive muscular dystrophy at the hospital of the Rockefeller Institute for Medical Research. All forms of treatment proved to be singularly ineffective. In the cases studied the amount of creatinine excreted daily remained remarkably constant, but there was a definite decrease in the amount. On the other hand, the quantity of creatine excreted was much more variable and in most cases was notably increased. They found, as others have done, that testosterone caused retention and storage of creatine but produced no significant change in excretion of creatinine.

Hoagland and others made a more detailed study of 6 boys with progressive muscular dystrophy from the Rockefeller Institute group and compared the findings with 5 normal boys. They concluded that the diminished excretion of creatinine in dystrophy was a more specific phenomenon because of its constancy than excessive excretion of creatine. Many other diseases and even physiologic states in normal human beings lead to an excessive output of creatine. The decrease in creatinine therefore is the most important test of activity of the disease in cases of progressive muscular dystrophy. Patients were given prolonged courses of gonadotropic and thyrotropic principles of the hypophysis and desoxycorticosterone acetate without any change being noted in the clinical state. In 1 case, however, there was improvement following the administration of testosterone propionate, this being the hormone known to cause retention of creatine.

Milhorat and Bartels in observing 15 patients with muscular dystrophy of a progressive type thought that the muscular changes closely resembled the dystrophy induced in animals by deprivation of tocopherol. In animals, when tocopherol is given orally, the creatinuria is promptly reduced and muscle function is restored. When the same vitamin is given parenterally to animals, no effect takes place. This observation led Milhorat and Bartels to suggest that some change takes place in tocopherol in the gastrointestinal tract. The authors believe that tocopherol forms a condensation product with some other substance and that this substance is inositol. When these two drugs were combined, effects were observed on the creatinuria in patients with muscular dystrophy and they suggested that the drug be given further trial.

MEDICATION BEFORE TONSILLECTOMY

To the Editor:—There is a difference of opinion among doctors as to whether or not patients should have premedication before anesthesia for tonsillectomy. What is the consensus on this matter?

F. L. Schade, M.D., Worthington, Minn.

ANSWER.—There is generally a difference of opinion among surgeons as to the desirability for premedication before tonsillectomy, both in adults and in children.

Most surgeons stanchly advocate premedication because of the four main functions of all premedications: (1) psychic depression or hypnosis, (2) heightening of the pain threshold, (3) reduction of reflex irritability and metabolism and (4) counteraction of undesirable side action of the anesthetic agent.

Those who oppose the use of premedication base their arguments mainly on the belief that its use favors the occurrence of postoperative complications. They feel that the depression of the cough reflex and the thickening of bronchial secretions favor the development of pulmonary complications and, further, in the presence of a diminished cough reflex there is increased likelihood of the aspiration of vomitus and blood. In addition, they contend that, in the presence of prolonged postoperative narcosis induced by premedications, postoperative bleeding may not be promptly discovered.

These objections are invalid if the premedication is properly used. This means individualization of dosage and, as important, that the medicine be given at the proper time preoperatively. If so given, its peak effectiveness is during operation, thus affording the maximum benefit, while its effects rapidly subside postoperatively, causing a minimum of undesirable after-effects.

It is generally agreed that premedication should be employed in tonsillectomy.

IMMUNE SERUM GLOBULIN FOR ORCHITIS OF MUMPS

To the Editor:—Is immune serum globulin of value in the prevention of orchitis in mumps in young adults?

James I. Knott, M.D., San Diego, Calif.

ANSWER.—It is extremely doubtful whether immune serum globulin would be of any benefit for the purpose suggested.

Human convalescent mumps serum has been used for the treatment of mumps and its complications as well as for prevention. However, it is questionable if there is a true specific serum which is of value for preventing or treating mumps orchitis

TREATMENT OF SPASTIC PARALYSIS

To the Editor:—Are there any recent developments in the treatment of spasticity in children?

Winifred Ingersoll, M.D., Laramie, Wyo.

ANSWER.—Recently there have been reports of improvements in some patients with spastic paralysis with the use of neostigmine and curare. Such treatment should be carried out, however, under the supervision of a neurologist.

NEW HORIZONS IN INDUSTRIAL HEALTH AND WELFARE

PROGRESS IN INDUSTRIAL HEALTH

REAR ADMIRAL JOEL T. BOONE (MC), U.S.N.
Washington, D. C.

This article and the articles by Andrew Fletcher and Boris Stern, which follow, were read in a panel discussion at the Seventh Annual Congress on Industrial Health in Boston, October 1. The Moderator was Dr. William A. Sawyer of Rochester, N. Y.

The progress made in industrial health in the United States over the past few decades has been continuous, although by no means regular and steady. The noteworthy advances that have been made are attributable primarily to the efforts, measures and programs undertaken in individual plants and in certain branches of industry. The value of an overall industrial health program applicable to all industries and occupations in the United States has never been convincingly sold to the public.

Some of the difficulties inherent in such a program are due to disagreement as to the relative responsibilities to the workers of management and organized labor, suspicion as to the motives of any health measures undertaken by management, inadequacy of health education, difficulties in delineating the functions of the medical and applied professions, confusion of "industrial health" with employee "morale and welfare" and, of course, the question of costs and who shall bear them. Nevertheless, the future of industrial health looks bright.

One of the industries in which industrial health progress has been wofully neglected is bituminous coal mining. This industry, which has been described as basic to the industrial economy of the nation, is scattered over twenty-six states, employs about 400,000 miners and is composed of about eight to nine thousand separate operations, ranging from the proverbial shoestring enterprise (the so-called "wagon mine," "truck mine" or "dog-hole") to the very large and integrated captive mine or big-scale operation. It is significant to note that 12 per cent of the mines produce about 72 per cent of the annual tonnage. On the other hand, 46.5 per cent of the mines produce only 2 per cent of the coal. Thus, although there is an extreme range in the size of mining operations, industrial health problems are common throughout the industry.

Certain aspects of the industrial health problems are encompassed in the demands which the labor unions made early this year during the negotiations with management over renewal of the union contract in the soft coal industry which expired March 31. Partly because of the inability of labor and management to agree on issues concerned with the financing and management of funds for medical and hospital care of the workers and for welfare and retirement benefits, the bituminous coal mines were closed down during April and a major part of May. When the negotiators advised the President of the United States that they could not come to an agreement, the President issued an executive order directing that the government technically take over operation of the mines. The responsibility for administering the operation of the mines was placed in the Interior Department, which is the government agency primarily concerned with natural resources.

The Secretary of the Interior, Hon. J. A. Krug, called on Admiral Ben Moreell of the Civil Engineer Corps, United States Navy, who had made a notable record in handling a similar situation in the oil industry last year, to become Federal Coal Mines Administrator. A week after government seizure Secretary Krug, with the assistance of Admiral Moreell, negotiated a contract with the miners' union, which became effective on May 29. Various provisions of this contract deal with health matters, among which is section 5, which reads as follows:

> The Coal Mines Administrator undertakes to have made a comprehensive survey and study of the hospital and medical facilities, medical treatment, sanitary and housing conditions in the coal mining areas. The purpose of this survey will be to determine the character and scope of improvements which should be made to provide the mine workers of the nation with medical, housing and sanitary facilities conforming to recognized American standards.

To carry out the provisions of section 5, the services of the Naval Medical Corps were sought, and Secretary Krug, with the approval of the President of the United States, selected Rear Admiral Joel T. Boone (MC), U.S.N., who was at the time inspector, Medical Department Activities, Pacific Coast, to serve as the director of the medical survey. Admiral Boone, with the assistance of a distinguished officer of the Navy Civil Engineer Corps, Commodore Charles T. Dickeman, began at once to plan and organize the survey.

It was apparent that to investigate all phases of the problem in detail through first-hand inspection of all the eight to nine thousand operating mines, or even of the approximately 3,500 mines, producing more than 50 tons daily, which were under seizure by the Coal Mines Administration, would be a task that could not be completed within a possible period of five or ten years and would therefore lose considerable value through the passage of time. It was decided, therefore to limit the survey to the more important aspects of the study and restrict the first-hand investigations to a percentage of the mines statistically selected by established sampling procedures. Accordingly, about 15 per cent of the mines producing 50,000 tons or more annually were chosen by a random sampling

---

This in no wise represents the final report of the Director of the Medical Survey.

method, the largest number of mines being chosen in areas where the number of working miners was the greatest, and the least number of mines being selected in areas where the number of working miners was the smallest. Agreement as to the mines selected was sought from management and labor.

Five teams of naval officers were organized to make the field inspections, each team being headed by a medical officer and including an engineer officer and a welfare and recreation officer. Each team, after being briefed on procedure and supplied with the questionnaire forms, was dispatched to one of the five areas into which the Coal Miners Administration had divided the country for administrative purposes. The territory comprising each of the five areas is as follows: Area 1, headquarters at Pittsburgh, comprising coal mining communities of Pennsylvania, northern West Virginia, Ohio and Maryland; area 2, headquarters at Ashland, Ky., comprising Kentucky, southern West Virginia, Virginia, Tennessee and Alabama; area 3, headquarters at Chicago, comprising Illinois, Indiana, Iowa and Michigan; area 4, headquarters at Kansas City, Mo., comprising Kansas, Missouri, Arkansas and Oklahoma, and area 5, headquarters at Denver, comprising all western bituminous coal producing states.

At the same time, in order to provide assurance that the mines selected for study were representative of the industry as a whole and to provide data for checking the accuracy of the information obtained by the field teams, simplified questionnaires were devised and sent to mine union officials and to operators of all mines of which the government had record. The director of the medical survey group and members of the headquarters staff went into the field to establish public relations, publicize the program, enlist the cooperation of agencies interested in the problem and obtain information which could be used in evaluating and interpreting the statistical data acquired by the field teams.

The fact that the survey is industrywide introduces many variable factors of geography, geology, climate, customs, laws and economics. On the other hand, the bituminous coal mining industry provides the advantages of fairly well standardized operating methods and uniform wage rates for employees, which, incidentally, are above the general average for industrial workers. The industry as a whole is highly competitive. Competition for markets exists between individual producers, as in other industries; between different groups of operators operating in different freight-rate zones, and between the industry as a whole and producers of other fuels, such as natural gas and petroleum.

Another pertinent characteristic of the industry is that, unlike manufacturing enterprises, the operator is limited in his selection of site, having to go where the coal seam is located. The coal entrepreneur must bring his equipment, electricity and supplies; he must, except in certain areas, bring in labor, and he must provide housing and other facilities and services at places where the coal lies.

This restricted choice of location has given rise to certain notable differences in the regional nature of coal mining communities. For example, in the Far West and in the southern Appalachian area coal mines are naturally situated away from centers of population, and, accordingly, the condition has given rise to coal "camps" which have become permanent communities. On the other hand, in the Midwestern states of Illinois and Indiana the coal deposits are located near established rural or urban towns or, in recent years, within easy reach from established settlements by motor vehicle and, consequently, no "company towns" exist. In the mineralized zones of Oklahoma and Arkansas underground coal mining has been for some time an irregular and seasonal source of employment, with the workers engaged during the remainder of the year in small farming ventures or in other part time occupations; consequently the miner population, rather than residing in close proximity to the mine, is scattered within a considerable radius. In the northern Appalachian area, particularly in Pennsylvania, the establishment of numerous cities, towns and other settlements resulting from the steady growth of industry, commerce and population has minimized the historic necessity of having company towns, and a number of the larger operators, over a period of years, have been selling their company-owned houses to the individual miners.

Under such a wide variety of conditions it becomes very difficult to assess the degree of responsibility of the operator, miner, state and local political bodies and others concerned in sanitation, water supply, sewage and refuse disposal, pure food and milk supplies and similar public health matters. It raises serious questions as to the methods of effecting higher standards of communal living.

No elaborate survey is required to substantiate the fact that some coal mining communities are maintained or, rather, are permitted to exist in a condition which is below any standard of living that is acceptable to the general American public. There are exceptional cases in which the houses are hazardous, the means for maintaining a comfortable temperature is lacking, the water supply is contaminated, garbage and refuse are not removed or are thrown to hogs, streams are polluted, screens and other measures of insect control are nonexistent, refrigeration is unknown, milk is disease laden and excreta and filth are close neighbors to the inhabitants.

There are a large number of "company towns" where one or several of such menaces to public health prevail and where measures to eliminate or control them are not being undertaken. In all fairness, however, it should be stated that there are also a number of company towns where living conditions are maintained on a par with the best of incorporated communities and where an active interest in public health is maintained.

The last sentence of section 5 of the Krug-Lewis agreement contains the phrase "medical, housing and sanitary facilities conforming to *recognized American standards.*"

As far as can be determined, no such "standards" exist, for it is not possible to find anywhere in the literature any definition of what constitutes recognized American standards; nor does it seem possible to measure accurately such a variable. The Medical Survey Group in this respect must be guided largely by personal observation rather than by statistical averages. What is decidedly substandard is relatively easy to recognize, and what patently appears above standard is readily discernible, but the accurate averaging of the broad range of conditions in between the two extremes defies objectivity. Until accurate yardsticks are devised, it must remain a matter of subjective judgment. One thing appears certain, and that is that conditions change with time and that the "standards" of today are not necessarily the "standards" of tomorrow.

The Medical Survey Group is not concerned with isolated instances but, rather, with the overall picture. It deals not with individual communities but with all coal communities. Whether or not the survey being conducted will substantiate the oft repeated allegations that the communities which owe their existence to coal mining are far below acceptable standards of living is conjectural at this time. It should be borne in mind, however, that similar allegations have been made with respect to other American industries.

Before proceeding further, the prevailing confusion regarding the provisions in the Krug-Lewis agreement for a medical and hospital fund and a welfare and retirement fund should be dissipated. The medical and sanitary survey which is called for has no direct relationship to these funds. The medical and hospital fund is to be made up of the deductions which the miners pay for medical care and hospitalization and which is now generally collected by management. This money will, at an agreed on date, be turned over to a group of trustees who are to be appointed by the head of the miners' union, the president of the United Mine Workers of America. The welfare and retirement fund, on the other hand, is a new fund created by the establishment of a royalty of 5 cents on each ton of coal mined and is being paid by the operators into a fund managed by a board of trustees made up of one appointee of the union, one appointee of the government as operator of the mines and a third member selected mutually by the other two members. This welfare and retirement fund is to be used for "making payments to miners, and their dependents and survivors, with respect to (1) wage loss not otherwise compensated at all or adequately under the provisions of federal or state law and resulting from sickness (temporary disability), permanent disability, death or retirement, and (2) other related welfare purposes, as determined by the trustees." Provision is made in the contract for the correlation of the two funds.

It is apparent from the wording of section 5 of the agreement between the government and the miners' union that the medical survey deals broadly with the healthfulness of coal mining communities and with the character of the medical attention given to the mine workers. Nevertheless, in an industry which has a long-established record for the highest frequency rate and the second highest severity rate of accidents—in other words, in a definitely hazardous industry, in which the employees work underground in limited artificial light, under conditions where air is artificially moved, humidity varies, considerable quantities of dust and gases are created, loud noises are produced, and erect posture in many instances is not possible—industrial health is of vital importance.

From personal observation and from a scanning of many of the reports which have been transmitted by the field teams of the Medical Survey Group, it is evident that medical practitioners in coal mining communities pay almost no attention to industrial health matters. It is regrettable to note that the mine physician who has taken the trouble to enter and familiarize himself with the mine, much less even to make a cursory occupational study of the men he treats, is a rarity. Further, only the exceptional ones attempt to familiarize themselves with industrial health studies which have been made in the coal mining industry by others. As for the practice of preventive medicine, there is a deplorable lack of interest. With few exceptions the mine physician appears to be concerned only with traumatic surgery and the general practice of medicine.

Prepayment medical plans and hospitalization plans are common in the coal industry. Regardless of geographic location, the miner expects deduction from his wages to be made for ordinary medical care, and the physician in mining communities, with few exceptions, receives his income directly or indirectly from the funds obtained in this way. Although there are many instances where the physician is selected by the miners through their union or through a committee, but with company approval, in most instances that have been observed the selection is made by the operating company, thus engendering a suspicion by the miner that in cases involving compensation for accidents or occupational illness the doctor is partial to the views of the management. This suspicion offers handcaps to any industrial health work he might endeavor to undertake.

If, for example, the physician should attempt to promote preemployment or preplacement examinations, his motives are suspected, as the labor unions have long contended that such examinations, except of the most cursory character, have been utilized to deny employment to eligible applicants. Consequently, under the present system of employing doctors at mines the physician is limited usually to "what he can see and feel."

The coal industry is sorely in need of industrial health studies and practice. It offers a challenge and a unique opportunity to the medical profession. With little difficulty the profession should be able to obtain the cooperation of management and labor in such a program. Here is a field where the lessons of job analysis learned from the many studies in other industries can be readily applied. Here is a field in which preplacement examinations, if in existence, could be an essential adjunct to the adequate practice of medicine, for the examiner in these cases is also the physician.

Of course, many industrial health studies have been made in bituminous coal mining, particularly with reference to the harmfulness of coal dust. But it is suggested that a wider and continuous program should supplement these earlier studies. Related industries have undertaken programs such as follows:

In addition to preplacement examinations, annual or other periodic examinations of employees are made. Illness and accident records are maintained and analyses made of them. Studies are conducted on fatigue, effect of the hours of work, relation of age to productivity, fumes from explosives and machinery and the effects of mine humidity, temperature, dust and low percentages of oxygen in air. Follow-ups are made of injury cases and illnesses.

There is no affirmative evidence, except in rare instances, that the company doctor or the practicing physician in mining communities goes into the mines for the express purpose of observing at first hand the working environment of his patients. He seemingly is not interested in, and does not help to promote or teach, first aid. He has only a casual interest in the local problems of nutrition and in his patients' housing, water supply, food and milk supply, sewage disposal, welfare and personal hygiene. He hardly ever, except in epidemics, maintains contact with or enlists the cooperation of public health officials and others concerned with stream pollution and similar matters which are beyond his own personal control.
